# List of Figures

2.1	A schematic representation of replica exchange molecular dynamics. . . . .	10
2.2	A typical free energy surface. Two free energy wells are separated by a barrier higher than $kT$ . . . . .	16
2.3	A schematic representation of metadynamics. The free energy well is gradually filled up with small Gaussians, and a transition is facilitated. . . . .	23
2.4	The configuration distributions under two Hamiltonians have no visible overlap as shown by solid black curves. A reference state (shown as the red curve) that has remarkable overlap with both states can be introduced to accelerate the convergence of the free energy calculations using, for instance, TP. .	28
2.5	State A and state B have only negligible overlap at high energy regions. The reference state generated by the mixing of state A and state B is characterized by $s$ . Increasing $s$ may lower the barrier between the dominant wells. . . . .	29
3.1	$P_0(\Delta U)$ , the Boltzmann factor $\exp(-\beta\Delta U)$ and their product, which is the integrand in Eq. 3.1.1.15. The low- $\Delta U$ tail of the integrand is poorly sampled with $P_0(\Delta U)$ and, therefore, is known with low statistical accuracy. However, it provides an important contribution to the integral. . . . .	34
3.2	A sample histogram in 2D space, for instance potential energy and a reaction coordinate $\xi$ . . . . .	41
3.3	The accumulation of work and heat along a nonequilibrium trajectory. The work is defined as the energy change when the coupling parameter switches from $\lambda_i$ to $\lambda_{i+1}$ with the coordinates fixed, while the dissipated heat is defined as the energy relaxation when the coordinate change with the coupling parameter fixed. . . . .	57

# Preface

Should we type some words here? Maybe not, 'coz we are not talkative persons.

## About the companion website

The website<sup>1</sup> for this file contains:

- A link to (freely downloadable) latest version of this document.
- Link to some implementations of WHAM.
- Other stuff might appear in the near future (HOPEFULLY!).

## Acknowledgements

- YM wants to express his special thanks to Dr. Bernard Brooks<sup>2</sup> and Dr. Gerhard König for helping him toddle in this field.
- We'll also like to thank Dr. Xiangyu Jia<sup>3</sup>, Dr. Meiting Wang, Dr. Wei Liu and Dr. Fengjiao Liu for many helpful discussions.

## Introduction

*“Everything should be made as simple as possible but not simpler.”*

– Albert Einstein,

Computer simulations of biological systems have made much progress in the past decades. A battery of methods at different levels of sophistication and complexity have been proposed.

However, we are still facing many difficulties in three aspects, i.e. Hamiltonians, sampling efficiency and postprocessing methods.[1]

In this booklet, we will not cover the whole spectrum of methods for enhanced samplings and free energy calculations, but only summarize some basic ideas. More complicated implementations of these methods, for instance 2-dimensional replica exchange molecular dynamics simulations, will not be discussed.

Recently, there is one special issue focusing on the methodologies of free energy calculations on Journal of Chemical Theory and Computation (Free Energy Calculations: Three Decades of Adventure in Chemistry and Biophysics, Journal of Chemical Theory and Computation, Volume 10, Issue 7, 2014, <http://pubs.acs.org/toc/jctcce/10/7>).

There are also some good papers for reference

- Andrew Pohorille, Christopher Jarzynski and Christophe Chipot, Good Practices in Free-Energy Calculations, Journal of Physical Chemistry B, 2010, 114 (32), 10235–10253
- Daniel M. Zuckerman, Equilibrium Sampling in Biomolecular Simulations, Annual Review of Biophysics, 2011, 40:41–62

There are also two books on this topic you might be interested in:

- Free Energy Calculations: Theory and Applications in Chemistry and Biology, Editors: Christophe Chipot, Andrew Pohorille, ISBN 978-3-540-38448-9, Springer-Verlag Berlin Heidelberg, 2007

- Free Energy Computations: A Mathematical Perspective, Author: Tony Lelievre, Gabriel Stoltz, Mathias Rousset, ISBN-13: 978-1848162471, Imperial College Press, 2010

Before we move into the major content of this booklet, we would like to review some fundamentals that underlie the methods introduced in the following chapters. The first one is the canonical partition function  $Q$  for Hamiltonian  $H(\mathbf{x}, \mathbf{p}_x)$ , which is defined as

$$\begin{aligned} Q(N, V, T) &= \frac{1}{h^{3N} N!} \iint \exp[-\beta H(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x \\ &= \frac{1}{\Lambda^{3N} N!} Z(N, V, T), \end{aligned} \quad (1.0.0.1)$$

where  $\mathbf{x}$  and  $\mathbf{p}_x$  are the coordinates and the conjugate momenta, respectively,

$$Z(N, V, T) = \int \exp(-\beta U(\mathbf{x})) d\mathbf{x} \quad (1.0.0.2)$$

is the configurational integral,  $\Lambda$  is the temperature-dependent de Broglie wavelength, and  $U(\mathbf{x})$  is the potential energy.

The partition function  $Q$  can also be defined in energy space as

$$Q(N, V, T) = \int \exp(-\beta E) \Omega_{tot}(N, V, E) dE, \quad (1.0.0.3)$$

where

$$\Omega_{tot}(N, V, E) = \frac{1}{h^{3N} N!} \iint_{V^N} \delta(H(\mathbf{x}, \mathbf{p}_x) - E) d\mathbf{x} d\mathbf{p}_x \quad (1.0.0.4)$$

is the complete density of states. Correspondingly, we can also define the configurational density of state as

$$\Omega_{con}(E) \propto \frac{1}{N!} \int_{V^N} \delta(U(\mathbf{x}) - E) d\mathbf{x}. \quad (1.0.0.5)$$

The Helmholtz free energy is defined in terms of the canonical partition function as

$$A = -\beta^{-1} \ln Q(N, V, T), \quad (1.0.0.6)$$

which connects thermodynamics and statistical mechanics. If we can estimate the value of  $Q$ , we can calculate  $A$ . However, evaluating  $Q$  is very difficult in most cases. Fortunately, we are only interested in the free energy differences,  $\Delta A$ , between two systems or two states of a system denoted by 0 and 1, respectively

$$\Delta A = -\beta^{-1} \ln Q_1/Q_0. \quad (1.0.0.7)$$

For most cases we are dealing with, the masses of particles in systems 0 and 1 are the same, Eq. 1.0.0.7 can be rewritten in terms of the configurational integrals  $Z_0$  and  $Z_1$

$$\Delta A = -\beta^{-1} \ln Z_1/Z_0. \quad (1.0.0.8)$$

In the following chapters, the systems 0 and 1 may differ in several ways. They may have different Hamiltonians,  $H_0$  and  $H_1$ . Or they may be characterized by different values of a macroscopic parameter, such as temperature. Finally, they may correspond to different regions in the phase space accessible to the system

$$Q_0 = \frac{1}{N!h^{3N}} \int_{\Gamma_0} \exp[-\beta H(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x \quad (1.0.0.9)$$

$$Q_1 = \frac{1}{N!h^{3N}} \int_{\Gamma_1} \exp[-\beta H(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x \quad (1.0.0.10)$$

where  $\Gamma_0$  and  $\Gamma_1$  may refer to different conformations of a flexible molecules, or the bound and unbound structures of a protein-ligand complex, etc.

In canonical ensemble (with  $NVT$  fixed), the probability of a microstate is

$$\rho(\mathbf{x}) = \frac{1}{Z} \exp(-\beta E(\mathbf{x})), \quad (1.0.0.11)$$

where  $E(\mathbf{x})$  is the potential energy of this microstate. With this probability we can calculate the expectation of any operator  $\hat{O}$  via

$$\langle O \rangle = \frac{\int \hat{O}(\mathbf{x}) \exp(-\beta E(\mathbf{x})) d\mathbf{x}}{Z}. \quad (1.0.0.12)$$

Besides state free energy, we may also be interested in free energy profiles along one or several degrees of freedom

$$\begin{aligned} A(\xi) &= -\beta^{-1} \ln Z(\xi) \\ &= -\beta^{-1} \ln \int \exp(-\beta U) \delta(\xi - \xi(\mathbf{x})) d\mathbf{x} \\ &= -\beta^{-1} \ln \int \exp(-\beta U(\xi(\mathbf{x}) = \xi)) |\mathbf{J}| dq_1 \cdots dq_{N-1}, \end{aligned} \quad (1.0.0.13)$$

where  $\mathbf{J}$  is the Jacobian matrix upon changing from Cartesian to generalized coordinates with its element defined as  $[\mathbf{J}(\mathbf{q})]_{ij} = \partial x_i / \partial q_j$  with  $q_N = \xi$ .  $|\mathbf{J}|$  is its determinant. Its gradient over  $\xi$  is

$$\begin{aligned} \frac{\partial A(\xi)}{\partial \xi} &= -\beta^{-1} \frac{\int \frac{\partial}{\partial \xi} (e^{-\beta U} |\mathbf{J}|) dq_1 \cdots dq_{N-1}}{\int e^{-\beta U} \delta(\xi - \xi(\mathbf{x})) d\mathbf{x}} \\ &= \frac{\int e^{-\beta U} \left[ \frac{\partial U}{\partial \xi} - \beta^{-1} \frac{1}{|\mathbf{J}|} \frac{\partial |\mathbf{J}|}{\partial \xi} \right] |\mathbf{J}| dq_1 \cdots dq_{N-1}}{\int e^{-\beta U} \delta(\xi - \xi(\mathbf{x})) d\mathbf{x}} \\ &= \frac{\int e^{-\beta U} \left[ \frac{\partial U}{\partial \xi} - \beta^{-1} \frac{\partial \ln |\mathbf{J}|}{\partial \xi} \right] |\mathbf{J}| dq_1 \cdots dq_{N-1}}{\int e^{-\beta U} \delta(\xi - \xi(\mathbf{x})) d\mathbf{x}} \\ &= \frac{\int e^{-\beta U} \left[ \frac{\partial U}{\partial \xi} - \beta^{-1} \frac{\partial \ln |\mathbf{J}|}{\partial \xi} \right] \delta(\xi - \xi(\mathbf{x})) d\mathbf{x}}{\int e^{-\beta U} \delta(\xi - \xi(\mathbf{x})) d\mathbf{x}} \\ &= \left\langle \frac{\partial U}{\partial \xi} - \beta^{-1} \frac{\partial \ln |\mathbf{J}|}{\partial \xi} \right\rangle_{\xi}. \end{aligned} \quad (1.0.0.14)$$

Here,  $-\frac{\partial U}{\partial \xi} + \beta^{-1} \frac{\partial \ln |\mathbf{J}|}{\partial \xi}$  is the generalized force on  $\xi$  to be averaged over the degrees of freedom other than  $\xi$  itself. Therefore,  $A(\xi)$  is called the potential of mean force. *Note: Some define the potential of mean force as  $\left\langle \frac{\partial U}{\partial \xi} \right\rangle_{\xi}$  only. But we do not strictly differentiate potential of mean force and free energy profile here.*

In order to illustrate how the simulations and free energy methods to be discussed below are used in real problems, let us take protein-ligand binding

as an example. The equilibrium constant,  $k_b$ , is defined as

$$K_b = \frac{[\text{P-L}]}{[\text{P}][\text{L}]}, \quad (1.0.0.15)$$

where  $[\text{P-L}]$ ,  $[\text{P}]$  and  $[\text{L}]$  are the equilibrium concentrations of the complex, protein and ligand, respectively. A standard binding free energy can be calculated via  $\Delta G_{\text{bind}} \equiv -\beta^{-1} \ln [K_b C^0]$ , where  $C^0$  is the standard state concentration of 1 mol/liter ( $\equiv 1/1661 \text{\AA}^3$ ).  $K_b$  can be expressed in terms of a ratio of configurational integrals as

$$K_b = \frac{1}{[L]} \frac{N \int_{\text{site}} d(\mathbf{1}) \int_{\text{bulk}} d(\mathbf{2}) \cdots \int_{\text{bulk}} d(\mathbf{N}) \int d\mathbf{X} e^{-\beta U}}{\int_{\text{bulk}} d(\mathbf{1}) \int_{\text{bulk}} d(\mathbf{2}) \cdots \int_{\text{bulk}} d(\mathbf{N}) \int d\mathbf{X} e^{-\beta U}}, \quad (1.0.0.16)$$

where  $U$  is the total potential energy of the system,  $(\mathbf{1})$ ,  $(\mathbf{2})$ ,  $\dots$ ,  $(\mathbf{N})$  and  $\mathbf{X}$  are the coordinates of the  $N$  ligand molecules and the remaining atoms, respectively. For simplicity, we omit the integrals over the  $(N-1)$  ligands in bulk, and we notice that  $\int_{\text{bulk}} d(\mathbf{1}) = V_{\text{bulk}} \int_{\text{bulk}} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*)$ . Then, we have

$$\begin{aligned} K_b &= \frac{1}{[L]} \frac{N \int_{\text{site}} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta U}}{V_{\text{bulk}} \int_{\text{bulk}} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta U}} \\ &= \frac{\int_{\text{site}} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta U}}{\int_{\text{bulk}} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta U}}. \end{aligned} \quad (1.0.0.17)$$

A direct calculation of this ratio is not easy. Practically, we can define a series of intermediate states. Thereupon, the calculation of this ratio can be facilitated by

$$K_b = \frac{\int_{\text{site}} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta U}}{Z_1} \times \frac{Z_1}{Z_2} \times \cdots \times \frac{Z_{n-1}}{Z_n} \times \frac{Z_n}{\int_{\text{bulk}} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta U}} \quad (1.0.0.18)$$

There are two categories of methods for computing  $K_b$ , i.e. the alchemical strategy[2] and the PMF-based strategy[3]. A comparison of these two

strategies can be found in Ref. [4, 5]. For each ratio in Eq. 1.0.0.18, we shall design a proper simulation and employ a suitable free energy method to calculate the free energy associated with it. Enhanced sampling might be necessary for convergence.

In alchemical strategy, the ligand is decoupled from its environment in the binding pocket and then appears in water. However, a series of steps with restraints on the conformation, translation and rotation are introduced. Equation 1.0.0.18 is now realized as

$$\begin{aligned}
K_b = & \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta U_1}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c]}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c+U_t]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c+U_t]}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c+U_t+U_r]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_1+U_c+U_t+U_r]}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_0+U_c+U_t+U_r]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_0+U_c+U_t+U_r]}}{\int_{bulk} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_0+U_c+U_t]}} \times \\
& \frac{\int_{bulk} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U_0+U_c+U_t]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U_0+U_c]}} \times \\
& \frac{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U_0+U_c]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U_1+U_c]}} \times \\
& \frac{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U_1+U_c]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta U_1}}. \tag{1.0.0.19}
\end{aligned}$$

In PMF-based strategy, the ligand is gradually pulled out of the binding pocket into water. Similarly, restraints on the conformation, translation and rotation should also be applied when pulling the ligand molecule. Equa-

tion 1.0.0.18 is now realized as

$$\begin{aligned}
K_b = & \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta U}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c]}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c+U_o]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c+U_o]}}{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c+U_o+U_a]}} \times \\
& \frac{\int_{site} d(\mathbf{1}) \int d\mathbf{X} e^{-\beta[U+U_c+U_o+U_a]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U+U_c+U_o]}} \times \\
& \frac{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U+U_c+U_o]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U+U_c]}} \times \\
& \frac{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta[U+U_c]}}{\int_{bulk} d(\mathbf{1}) \delta(\mathbf{r}_1 - \mathbf{r}^*) \int d\mathbf{X} e^{-\beta U}}. \tag{1.0.0.20}
\end{aligned}$$

It is worth emphasizing that this PMF-based strategy does not yield the real entry/escaping pathways.

## 2

# Enhanced Sampling

*“Keep the smart guys around you.”*

– Bernard R. Brooks

From the definition, the free energy of a specific system is dominated by phase space regions with low energy. However, these regions might be separated by high energy barriers. Transitions among these potential energy wells are often hindered by these barriers. According to the Boltzmann’s Law, the probability of a sample  $\mathbf{R}$  being visited is proportional to the Boltzmann’s factor  $\exp[-\beta E(\mathbf{R})]$ , where  $\beta = 1/kT$  is called the inverse temperature.  $k$  is the Boltzmann constant and  $T$  is the temperature. According to some experience, in a 100 ns simulation, the system can overcome a barrier of 10 kT, which is 6 kcal/mol at room temperature (300 K). If the barrier is 1.5 kcal/mol higher, it takes about 1  $\mu$ s (10 times longer) in average for the system to go over the barrier. If the barrier height reaches 9 kcal/mol, it takes 10  $\mu$ s. And so on. With modern computers, the longest all-atom molecular dynamics simulation for biological systems is probably done by D.E. Shaw, which was on a time scale of 1 ms on a special-purpose computer “Anton”. For most classical molecular dynamics simulations, the time scales are normally several  $\mu$ s to tens of  $\mu$ s. For simulations using expensive Hamiltonians, such as in QM/MM simulations, the time scales that can be reached are usually three orders shorter. Clearly, molecular dynamics simulations are plagued by a timescale problem. In order to observe abundant transitions among these energy minima, which is required by free energy calculations, enhanced samplings are often indispensable. As shown in the Boltzmann’s factor, the essential quantity that determines the rate of transitions is  $\beta E$ . In order to accelerate the phase space sampling, we can either increase the temperature or decrease the energy barrier. All the methods shown below can be classified into these two categories.

## 2.1 Replica Exchange Molecular Dynamics

### 2.1.1 Temperature-Replica Exchange Molecular Dynamics

Temperature replica exchange molecular dynamics (T-REMD) is one class of parallel tempering methods developed by Sugita and Okamoto in 1999[6] based on many ideas in a category of methods called *generalized-ensemble algorithm*. It is an extension of the well-known simulated annealing method. The basic idea of REMD is schematically summarized in Fig. 2.1. In REMD, the system is replicated into  $M$  *non-interacting* copies (replicas). Each replica is coupled to a bath at temperature  $T_m$ , ( $m = 1, \dots, M$ ). At a certain time, the system is at state  $X$ , which can be denoted as  $X = (x_1^{[i(1)]}, \dots, x_M^{[i(M)]}) = (x_{m(1)}^{[1]}, \dots, x_{m(M)}^{[M]})$ . Here, we used  $i$  and  $m$  to label the replica and the temperature respectively. Because the replicas are non-interacting, the weight-factor for a state  $X$  in this generalized ensemble is a direct product of the Boltzmann factors for each replica, i.e.

$$W_{REM}(X) = \prod_{m=1}^M \exp(-\beta_m H(q^{[i(m)]}, p^{[i(m)]})) = \prod_{i=1}^M \exp(-\beta_{m(i)} H(q^{[i]}, p^{[i]})) \quad (2.1.1.1)$$

Figure 2.1: A schematic representation of replica exchange molecular dynamics.

Now, we exchange the temperatures of a pair of replicas

$$\begin{cases} x_m^{[i]} \equiv (q^{[i]}, p^{[i]})_m \Rightarrow x_n^{[i]'} \equiv (q^{[i]}, p^{[i]'})_n \\ x_n^{[j]} \equiv (q^{[j]}, p^{[j]})_n \Rightarrow x_m^{[j]'} \equiv (q^{[j]}, p^{[j]'})_m \end{cases}, \quad (2.1.1.2)$$

where

$$\begin{cases} p^{[i]'} \equiv \sqrt{\frac{T_n}{T_m}} p^{[i]} \\ p^{[j]'} \equiv \sqrt{\frac{T_m}{T_n}} p^{[j]} \end{cases}. \quad (2.1.1.3)$$

The exchange rule is not trivial. In order for this exchange process to converge towards an equilibrium distribution, it is sufficient to impose the detailed balance condition on the transition probability  $w(X \rightarrow X')$ :

$$W_{REM}(X)w(X \rightarrow X') = W_{REM}(X')w(X' \rightarrow X). \quad (2.1.1.4)$$

Then we have

$$\begin{aligned} & \frac{w(X \rightarrow X')}{w(X' \rightarrow X)} \\ &= \frac{W_{REM}(X')}{W_{REM}(X)} \\ &= \frac{\exp(-\beta_m H(q^{[j]}, p^{[j]'})) \exp(-\beta_n H(q^{[i]}, p^{[i]'}))}{\exp(-\beta_m H(q^{[i]}, p^{[i]}) \exp(-\beta_n H(q^{[j]}, p^{[j]}))} \\ &= \frac{\exp\{-\beta_m [K(p^{[j]'} + U(q^{[j]})) - \beta_n [K(p^{[i]'} + U(q^{[i]}))]\}}{\exp\{-\beta_m [K(p^{[i]} + U(q^{[i]})) - \beta_n [K(p^{[j]} + U(q^{[j]}))]\}} \\ &= \frac{\exp\{-\beta_m [\frac{T_m}{T_n} K(p^{[j]} + U(q^{[j]})) - \beta_n [\frac{T_n}{T_m} K(p^{[i]} + U(q^{[i]}))]\}}{\exp\{-\beta_m [K(p^{[i]} + U(q^{[i]})) - \beta_n [K(p^{[j]} + U(q^{[j]}))]\}} \\ &= \frac{\exp\{-\beta_n K(p^{[j]}) - \beta_m K(p^{[i]})\} \exp\{-\beta_m U(q^{[j]}) - \beta_n U(q^{[i]})\}}{\exp\{-\beta_m K(p^{[i]}) - \beta_n K(p^{[j]})\} \exp\{-\beta_m U(q^{[i]}) - \beta_n U(q^{[j]})\}} \\ &= \exp\{-\Delta\}. \end{aligned} \quad (2.1.1.5)$$

where  $\Delta = [\beta_n - \beta_m] [U(q^{[i]}) - U(q^{[j]})]$ . It can be seen that the kinetic energy terms are fully canceled out. This can be satisfied by the usual Metropolis criterion:

$$w(X \rightarrow X') \equiv w\left(x_m^{[i]} \middle| x_n^{[j]}\right) = \begin{cases} 1, & \text{if } \Delta \leq 0 \\ \exp(-\Delta), & \text{if } \Delta > 0 \end{cases} \quad (2.1.1.6)$$

After long time simulations, all the replicas have arrived at a global equilibrium. In order to calculate the the free energy or the ensemble average of an operator  $\hat{A}$  at  $T_m$ , we can extract all the snapshots that have a temperature  $T_m$  from  $M$  trajectories, if this temperature was among the  $M$  chosen temperatures. However, the optimal way is to use Weighted Histogram Analysis Method in Section 3.1.4 or the Multistate Bennett Acceptance Ratio method in Section 3.1.5.

### 2.1.2 Hamiltonian-Replica Exchange Molecular Dynamics

Another type of REMD simulation is called Hamiltonian replica exchange molecular dynamics (H-REMD), in which each replicas has its own Hamiltonian, but is coupled to the same temperature. One example is the H-REMD

simulation for a torsional angle. The  $m$ th replica has a torsional energy term of

$$H_m(\phi) = \lambda(m) \sum_n (V_n/2) (1 + \cos[n\phi - \delta]), \quad (2.1.2.1)$$

where  $\lambda$  is a control parameter.  $\lambda(0) = 1$  corresponds to the unbiased state and at  $\lambda(M)$  (usually  $\lambda(M) = 0$ ) the torsional motion of this dihedral angle has a smaller barrier.

Another example of HREMD is pH-REMD, in which each replica is coupled with different pH of the solution. In other words, the chemical potential of hydronium in each replica is different. Therefore, the protonation states (or probability of being protonated or deprotonated) of titratable residues in each replica may differ from those in other replicas. In the simulations, the protonation states of titratable residues have their protonation states alternated according to the Metropolis criterion

$$P = \begin{cases} 1, & \text{if } \Delta G_{P_A \rightarrow P_A H^+} \leq 0 \\ \exp(-\beta \Delta G_{P_A \rightarrow P_A H^+}), & \text{if } \Delta G_{P_A \rightarrow P_A H^+} > 0 \end{cases} \quad (2.1.2.2)$$

using Monte Carlo. The derivation of  $\Delta G_{P_A \rightarrow P_A H^+}$  is shown below.

Free energy of molecule A in solution with a concentration  $[A]$  can be written as

$$\Delta G_A = \Delta G_A^0 + \beta^{-1} \ln \frac{[A]}{C_0},$$

in which  $\Delta G_0$  is the free energy of molecule A at the standard state  $C_0$ , i.e. 1 mol/L. The free energy change for a reaction

can be written as

$$\Delta G = \Delta G_C - \Delta G_A - \Delta G_B = \Delta G_0 + \beta^{-1} \ln \frac{[C] C_0}{[A][B]}.$$

At equilibrium, the free energy change is zero, we have

$$\Delta G_0 = -\beta^{-1} \ln \frac{[C] C_0}{[A][B]}, \quad (2.1.2.3)$$

in which  $[A][B]/[C]C_0$  is called the dissociation constant  $K_a$ . So,

$$\Delta G_0 = \beta^{-1} \ln K_a. \quad (2.1.2.4)$$

Titration of a residue in a real protein can be written as

with

$$K_a = \frac{[P_A][H^+]}{[P_AH^+]C_0}$$

The fraction of the deprotonated species is calculated as

$$\begin{aligned} f_{[P_A]} &= \frac{[P_A]}{[P_A] + [P_AH^+]} \\ &= \frac{1}{1 + \frac{[P_AH^+]}{[P_A]}} \\ &= \frac{1}{1 + \frac{[P_A][H^+]}{C_0K_a[P_A]}} \\ &= \frac{1}{1 + \frac{1}{C_0K_a}[H^+]} \\ &= \frac{1}{1 + \frac{1}{K_a}10^{-pH}} \end{aligned} \quad (2.1.2.5)$$

We can check the asymptotic behavior of this equation. At strong acidic condition ( $pH = -\infty$ ),  $f_{\{P_A\}} = 0$ , indicating that the residue is 100 percent protonated. While at an extremely basic condition ( $pH = \infty$ ),  $f_{\{P_A\}} = 1$ . This residue is 100 percent deprotonated. From the Henderson–Hasselbalch (HH) equation, the  $pK_a$  can be determined by the  $pH$  of the state when  $[P_A]/[P_AH^+] = 1$  (the isoelectric point)

$$\begin{aligned} pK_a &= -\log K_a \\ &= -\log \frac{[P_A]}{[P_AH^+]} - \log \frac{[H^+]}{C_0} \\ &= -\log \frac{[P_A]}{[P_AH^+]} + pH. \end{aligned} \quad (2.1.2.6)$$

The  $pK_a$  of each residue in a dipeptide has been determined by experiment. However, when this residue is located in a certain protein, its  $pK_a$  is different from that in the dipeptide. The difference is called the  $pK_a$  shift. Instead of measuring the  $pK_a$  for a residue in a protein, we are more interested in calculating/measuring the titration curve, which is the fraction of the deprotonated state as a function of pH. From Eq. 2.1.2.5,  $f_{[P_A]}$  can be easily calculated if we know  $K_a$  or equivalently the standard free energy change of protonation in Eq. 2.1.2.4. The standard free energy can be calculated from the partition functions as

$$\begin{aligned}
\Delta G_0 &= -\beta^{-1} \ln \frac{Q_{PAH^+}}{Q_{PA} Q_{H^+}} \\
&= -\beta^{-1} \ln \frac{\iint \exp(-\beta E_{PAH^+}) dR_H dR_o}{Q_{H^+} \int \exp(-\beta E_{PA}) dR_o}
\end{aligned}$$

Generally, the absolute value of  $\Delta G_0$  is hardly computable. A relative protonation free energy  $\Delta\Delta G$  is preferred and is more reliable. Theoretically, the reference state can be any state you like. But the protonation free energy of the dipeptide at  $pK_a$  is often used. The reference protonation process can be written as

The reference free energy change is

$$\begin{aligned}
&\Delta\Delta G_0 \\
&= \Delta G_0 - \Delta G_0^{ref} \\
&= -\beta^{-1} \ln \frac{\iint \exp(-\beta E_{PAH^+}) dR_H dR_o}{Q_{H^+} \int \exp(-\beta E_{PA}) dR_o} \frac{Q_{H^+} \int \exp(-\beta E_A) dR_o}{\iint \exp(-\beta E_{AH^+}) dR_H dR_o} \\
&= -\beta^{-1} \ln \frac{\iint \exp(-\beta E_{PAH^+}) dR_H dR_o \int \exp(-\beta E_A) dR_o}{\int \exp(-\beta E_{PA}) dR_o \iint \exp(-\beta E_{AH^+}) dR_H dR_o} \\
&= -\beta^{-1} \ln \frac{\iint \exp \left[ -\beta \left( E_{PAH^+}^{bond} + E_{PAH^+}^{QM} + E_{PAH^+}^{ele} \right) \right] dR_H \exp \left( -\beta E_{PAH^+}^{other} \right) dR_o}{\iint \exp \left[ -\beta \left( E_{AH^+}^{bond} + E_{AH^+}^{QM} + E_{AH^+}^{ele} \right) \right] dR_H \exp \left( -\beta E_{AH^+}^{other} \right) dR_o} \\
&\quad \cdot \frac{\int \exp(-\beta E_A) dR_o}{\int \exp(-\beta E_{PA}) dR_o}, \tag{2.1.2.7}
\end{aligned}$$

where  $R_H$  is the coordinates of the specific  $H$  atom and the other degrees-of-freedom (DoF) are denoted as  $R_o$ .  $E^{bond}$  and  $E^{ele}$  are the bonded energy and electrostatic interaction energy related to this  $H$  atom, respectively.  $E^{QM}$  is the energy correction that *may* be required if the molecular mechanical Hamiltonian cannot well capture the energy of the system, such as the missing of charge transfer effect. The sum of the remaining energy term is denoted as  $E^{other}$ , which does not explicitly depend on the position of this specific  $H$  atom. Eq. 2.1.2.7 is not ready to be computed before some approximations are adopted.

*First*, we assume that the total energy can be well described by the MM Hamiltonians for both the state interested in and the reference state. Therefore,

$$E_{PAH^+}^{QM} = E_{AH^+}^{QM} = Const,$$

and they can be removed from the integral.

*Second*, the bonded terms involving hydrogen atoms are usually constrained in the simulations. Therefore, the hydrogen atom in question has only one position and  $E^{bond} = 0$ . Now, the relative protonation free energy can be simplified as

$$\Delta\Delta G_0 = -\beta^{-1} \ln \frac{\int \exp(-\beta E_{P_A H^+}^{ele}) \exp(-\beta E_{P_A H^+}^{other}) dR_O}{\int \exp(-\beta E_{A H^+}^{ele}) \exp(-\beta E_{A H^+}^{other}) dR_O} \cdot \frac{\int \exp(-\beta E_A) dR_O}{\int \exp(-\beta E_{P_A}) dR_O}. \quad (2.1.2.8)$$

Note that  $E_A = E_{A H^+}^{other}$  and  $E_{P_A} = E_{P_A H^+}^{other}$ , we have

$$\Delta\Delta G_0 = -kT \ln \frac{\int \exp(-\beta E_{P_A H^+}^{ele}) \exp(-\beta E_{P_A}) dR_O}{\int \exp(-\beta E_{P_A}) dR_O} \quad (2.1.2.9)$$

$$\cdot \frac{\int \exp(-\beta E_A) dR_O}{\int \exp(-\beta E_{A H^+}^{ele}) \exp(-\beta E_A) dR_O} \quad (2.1.2.10)$$

$$\begin{aligned} &= -\beta^{-1} \ln \left\langle \exp(-\beta E_{P_A H^+}^{ele}) \right\rangle_{P_A} \\ &\quad + \beta^{-1} \ln \left\langle \exp(-\beta E_{A H^+}^{ele}) \right\rangle_A \\ &= \Delta G_{P_A H^+}^{ele} - \Delta G_{A H^+}^{ele} \end{aligned} \quad (2.1.2.11)$$

Therefore,

$$-\beta^{-1} \ln 10 \cdot pK_a = \Delta G_{P_A H^+}^{ele} - \Delta G_{A H^+}^{ele} - \beta^{-1} \ln 10 \cdot pK_a^{ref}.$$

Using Eq. 2.1.2.6, at a certain pH the free energy difference between the deprotonated and the protonated state can be written as

$$\Delta G_{P_A \rightarrow P_A H^+} = \Delta G_{P_A H^+}^{ele} + \beta^{-1} (pH - pK_a^{ref}) \ln 10 - \Delta G_{A H^+}^{ele}.$$

In the above equation,  $\Delta G_{A H^+}^{ele}$  can be obtained from a free energy calculation of the model system by alchemically annihilation of the proton. However,  $\Delta G_{P_A H^+}^{ele}$  is unknown. Approximately, it can be replaced with  $\Delta H_{P_A H^+}^{ele}$  averaged over a few snapshots.[7] In order to accelerate the convergence, this pH-REMD is often coupled with other enhanced simulation methods, such as T-REMD[7] and EDS-REMD[8] (see section 2.7).

## 2.2 Umbrella Sampling

Umbrella Sampling method was proposed by Torrie and Valleau in 1977,[9] and is still widely used nowadays. Suppose we are studying a transition process between two states such as conversion between two dominant conformations or a chemical reaction, and these two states are separated by a high barrier relative to  $kT$ . Therefore, the transition is a rare event. A schematic representation of the free energy landscape is shown in Fig. 2.2.

Figure 2.2: A typical free energy surface. Two free energy wells are separated by a barrier higher than  $kT$ .

Sometimes, we are interested in not only these two dominant states but also the whole pathway. Usually, we define a reaction coordinate  $\xi$  and calculate the potential of mean force along this reaction coordinate from the “reactant” to the “product”. The reaction coordinate can be either real coordinates such as the difference of bond lengths in, for example, an  $S_N2$  reaction, or a thermodynamics coupling parameter ( $\lambda$ ) that defines an unphysical path. However, if we run a simulation with the reaction coordinate initially set to the transition state or the slope, the system will quickly roll back to the “reactant” or the “product” state in order to reduce the free energy. The consequence is that phase space outside the “reactant” and “product” regions cannot be sampled sufficiently to yield accurate free energy profile in a brute force simulation. In order to enhance the exploration in these regions, a series of artificial biasing potentials as (usually harmonic) functions of  $\xi$  can be added to the potential energy. Simulations are performed on these potential energy surfaces

$$U_i(\mathbf{R}) = U_0(\mathbf{R}) + \Delta U_i(\xi). \quad (2.2.0.1)$$

Each biased simulation is called a *window*. The strengths of the biases should be strong enough to maintain the system in the vicinity of where you are interested in, and also should be weak enough that the system can have significant overlap in two adjacent windows. After all the simulations, the (biased) distribution of the samples in the whole region should be as flat as possible. Ensemble average under  $U_0$  can be calculated from the ensembles

generated under the biased Hamiltonians  $U$  via

$$\begin{aligned}
 \langle X(\mathbf{R}) \rangle_0 &= \frac{\int X(\mathbf{R}) \exp[-\beta U_0(\mathbf{R})] d\mathbf{R}}{\int \exp[-\beta U_0(\mathbf{R})] d\mathbf{R}} \\
 &= \frac{\int X(\mathbf{R}) \exp[\beta \Delta U_i(\mathbf{R})] \exp[-\beta U_i(\mathbf{R})] d\mathbf{R}}{\int \exp[\beta \Delta U_i(\mathbf{R})] \exp[-\beta U_i(\mathbf{R})] d\mathbf{R}} \\
 &= \frac{\langle X \exp(\beta \Delta U_i) \rangle_i}{\langle \exp(\beta \Delta U_i) \rangle_i}. \tag{2.2.0.2}
 \end{aligned}$$

Better postprocessing methods are the Weighted Histogram Analysis Method and the Multistate Bennett Acceptance Ratio method (to be discussed in Section 3.1.4 and 3.1.5).

### 2.3 Adaptive Biasing Force Method

If the conditional gradient of the free energy with respect to a reaction coordinate (mean force) over the equilibrium distribution of the system *restricted* to the hypersurface where the reaction coordinate is constant can be computed, the free energy profile along this specific reaction coordinate can be readily obtained by thermodynamic integration. In the following, we shall follow the derivation by Ciccotti et al.[10] For a system under molecular constraints,  $\sigma_j(x) = 0$ ,  $j = 1, \dots, M$ , the probability density reads

$$\rho(x) = Z_\sigma^{-1} e^{-\beta V(x)} \prod_{j=1}^M \delta(\sigma_j(x)), \quad (2.3.0.1)$$

in which

$$Z_\sigma = \int e^{-\beta V(x)} \prod_{j=1}^M \delta(\sigma_j(x)) dx \quad (2.3.0.2)$$

is the configuration integral. By definition, the free energy associated with the vectorial reaction coordinate  $q(x) = (q_1(x), \dots, q_N(x))$  is given by

$$F(z) := -\beta^{-1} \ln Z_\sigma^{-1} \int e^{-\beta V(x)} \prod_{k=1}^N \delta(q_k(x) - z_k) \prod_{j=1}^M \delta(\sigma_j(x)) dx, \quad (2.3.0.3)$$

where  $z = (z_1, \dots, z_N)$ . By differentiating both sides with respect to  $z_j$ , we find

$$\frac{\partial F(z)}{\partial z_j} = -\beta^{-1} e^{\beta F(z)} \cdot Z_\sigma^{-1} \int e^{-\beta V(x)} \frac{\partial}{\partial z_j} \prod_{k=1}^N \delta(q_k(x) - z_k) \times \prod_{j=1}^M \delta(\sigma_j(x)) dx \quad (2.3.0.4)$$

Notice that

$$\begin{aligned} & \frac{\partial}{\partial z_j} \prod_{k=1}^N \delta(q_k(x) - z_k) \times \prod_{j=1}^M \delta(\sigma_j(x)) \\ &= -\delta'(q_j(x) - z_j) \prod_{k \neq j} \delta(q_k(x) - z_k) \times \prod_{j=1}^M \delta(\sigma_j(x)) \\ &= -(b_j(x) \cdot \nabla \delta(q_j(x) - z_j)) \prod_{k \neq j} \delta(q_k(x) - z_k) \times \prod_{j=1}^M \delta(\sigma_j(x)) \\ &= -b_j(x) \cdot \nabla \left( \prod_{k=1}^N \delta(q_k(x) - z_k) \times \prod_{j=1}^M \delta(\sigma_j(x)) \right) \end{aligned} \quad (2.3.0.5)$$

where  $b_j(x), j = 1, \dots, N$  are vector fields satisfying

$$b_j(x) \cdot \nabla \sigma_k(x) = 0, \quad \forall j = 1, \dots, N, k = 1, \dots, M \quad (2.3.0.6)$$

and

$$b_j(x) \cdot \nabla q_k(x) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{otherwise} \end{cases}. \quad (2.3.0.7)$$

Thereby,

$$\begin{aligned} & \frac{\partial F(z)}{\partial z_j} \\ &= -\beta^{-1} e^{\beta F(z)} \cdot Z_\sigma^{-1} \int e^{-\beta V(x)} b_j(x) \nabla \left( \prod_{k=1}^N \delta(q_k(x) - z_k) \prod_{j=1}^M \delta(\sigma_j(x)) \right) dx \\ &= e^{\beta F(z)} \cdot Z_\sigma^{-1} \int e^{-\beta V(x)} \left( b_j(x) \cdot \nabla V(x) - \beta^{-1} \nabla \cdot b_j(x) \right) \\ &\quad \times \prod_{k=1}^N \delta(q_k(x) - z_k) \prod_{j=1}^M \delta(\sigma_j(x)) dx \end{aligned} \quad (2.3.0.8)$$

after integration by parts. After rearrangement, the gradient of  $F(z)$  (i.e. the mean force) can be expressed as

$$\frac{\partial F}{\partial z_j} = \left\langle b_j(x) \cdot \nabla V - \beta^{-1} \nabla \cdot b_j(x) \right\rangle_{q(x)=z, \sigma(x)=0}, \quad (2.3.0.9)$$

where  $\langle \cdot \rangle_{q(x)=z, \sigma(x)=0}$  denotes the conditional average under the constraints  $q(x) = z$ ,  $\sigma(x) = 0$ . For any function  $f(x)$

$$\langle f \rangle_{q(x)=z, \sigma(x)=0} = \frac{\int f(x) e^{-\beta V(x)} \prod_{k=1}^N \delta(q_k(x) - z_k) \prod_{j=1}^M \delta(\sigma_j(x)) dx}{\int e^{-\beta V(x)} \prod_{k=1}^N \delta(q_k(x) - z_k) \prod_{j=1}^M \delta(\sigma_j(x)) dx}. \quad (2.3.0.10)$$

Being “restricted” here is different from being “constrained”. In the latter, there is an additional condition that the velocity of this reaction coordinate must be set to zero. In the standard Blue Moon sampling method developed by Carter et al.[11], constrained molecular dynamics is utilized to compute the conditional expectation in Eq. 2.3.0.10. However, it introduces additional constraints on the momenta, which has to be removed. Therefore, computing the mean force from a constrained ensemble, a correction factor (denoted as  $|Z|^{-1/2}$  in Ref. [11]) must be introduced, which arises from performing the momentum integration in the ensemble average. In addition, constrained simulation may cause quasinonergodic effect, in particular when multiple reaction pathways are present. Therefore, constrained simulation is not recommended.

Alternatively, adaptive biasing force (ABF) method, which was proposed by Darve and Pohorille in 2001[12] and reformulated in 2008[13], can be used for the calculations of free energy profiles. It applies to unconstrained simulations, as well as constrained simulations. In ABF, an external force,  $-\langle F_\xi |_{\xi^*} \rangle \nabla \xi$ , that counteracts the mean force is applied. The net result of

this procedure is that, after a brief equilibrium, the average force acting on  $\xi$  is close to zero and the system undergoes barrierless diffusionlike motion along the order parameter. This means that the sampling of  $\xi$  becomes uniform.

We denote by  $\boldsymbol{\xi}$  the vector of all order parameters  $\xi_i$ ,  $i = 1, \dots, N_\xi$ . The free energy  $A(\boldsymbol{\xi})$  is defined as

$$A(\boldsymbol{\xi}) = -\ln \int e^{-H(\mathbf{x})} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}. \quad (2.3.0.11)$$

$\beta$  has been absorbed. Now define a thin matrix  $\mathbf{W}$  with  $N_\xi$  columns, which satisfies

$$\mathbf{J}_\xi \mathbf{W} = \mathbf{I}, \quad (2.3.0.12)$$

where  $\mathbf{J}_\xi$  is a fat matrix with its element defined by

$$[\mathbf{J}_\xi]_{ij} = \frac{\partial \xi_i}{\partial x_j}, \quad (2.3.0.13)$$

and  $\mathbf{I}$  is a unit matrix. Using the definition of ensemble average and integration by parts, we find

$$\begin{aligned} \left\langle \mathbf{W}^t \nabla U - (\nabla \cdot \mathbf{W})^t \right|_\xi \rangle &= \frac{\int (\mathbf{W}^t \nabla U - (\nabla \cdot \mathbf{W})^t) e^{-U} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}}{\int e^{-U(\mathbf{x})} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}} \\ &= \frac{-\int (\nabla \cdot (e^{-U} \mathbf{W}))^t \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}}{\int e^{-U(\mathbf{x})} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}} \\ &= \frac{\int e^{-U} \mathbf{W}^t \nabla \left( \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) \right) d\mathbf{x}}{\int e^{-U(\mathbf{x})} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}}. \end{aligned} \quad (2.3.0.14)$$

Let us choose an index  $i$  ( $1 \leq i \leq N_\xi$ ) and focus on  $\partial A / \partial \xi_i$ . Only row  $i$  of  $\mathbf{W}^t$ ,  $w_i$ , needs to be considered. The gradient can be computed as

$$\nabla \left( \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) \right) = \sum_{k=1}^{N_\xi} \delta'(\xi_k(\mathbf{x}) - \xi_k) \prod_{j \neq k} \delta(\xi_j - \xi_j(\mathbf{x})) \nabla \xi_k. \quad (2.3.0.15)$$

Since we have  $\nabla \xi_k w_i = \delta_{ik}$ ,

$$w_i \cdot \nabla \left( \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) \right) = \delta'(\xi_i(\mathbf{x}) - \xi_i) \prod_{j \neq i} \delta(\xi_j - \xi_j(\mathbf{x})). \quad (2.3.0.16)$$

Therefore, the  $i$ th component of  $\left\langle \mathbf{W}^t \nabla U - (\nabla \cdot \mathbf{W})^t \right|_\xi \rangle$  is

$$\frac{\int e^{-U} \delta'(\xi_i(\mathbf{x}) - \xi_i) \prod_{j \neq i} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}}{\int e^{-U(\mathbf{x})} \prod_{j=1}^{N_\xi} \delta(\xi_j - \xi_j(\mathbf{x})) d\mathbf{x}} = \frac{\partial A}{\partial \xi_i}, \quad (2.3.0.17)$$

where a property of  $\delta$  function

$$\int f(x)\delta'(x) dx = - \int f'(x)\delta(x) dx \quad (2.3.0.18)$$

has been used. This proves

$$\nabla_{\xi} A = \left\langle \mathbf{W}^t \nabla U - (\nabla \cdot \mathbf{W})^t \Big|_{\xi} \right\rangle. \quad (2.3.0.19)$$

This can be used in conjunction with the calculations of first and second spatial derivatives.

For multiple reaction coordinates, the calculation of  $\nabla_{\xi} A$  can requires only first derivatives by observing that, with  $\mathbf{J}(\mathbf{w})_{ij} = \frac{\partial w_i}{\partial x_j}$ ,

$$\begin{aligned} \left\langle \frac{d}{dt}(w_i \cdot \mathbf{p}) \Big|_{\xi} \right\rangle &= \left\langle \mathbf{p}^t \mathbf{M}^{-1} \mathbf{J}(w_i)^t \mathbf{p} - w_i \cdot \nabla U \Big|_{\xi} \right\rangle \\ &= \left\langle -w_i \cdot \nabla U + \text{Tr}(\mathbf{J}(w_i)) \Big|_{\xi} \right\rangle \\ &= - \left\langle w_i \cdot \nabla U - \nabla \cdot w_i \Big|_{\xi} \right\rangle \\ &= - \frac{\partial A}{\partial \xi_i}. \end{aligned} \quad (2.3.0.20)$$

During the deviation, the equality

$$\int \mathbf{u}^t \mathbf{B} \mathbf{u} e^{-\mathbf{u}^t \mathbf{A} \mathbf{u}} d\mathbf{u} = \frac{1}{2} \text{Tr}(\mathbf{A}^{-1} \mathbf{B}) \int e^{-\mathbf{u}^t \mathbf{A} \mathbf{u}} d\mathbf{u} \quad (2.3.0.21)$$

has been used with  $\mathbf{u} = \mathbf{p}$ ,  $\mathbf{B} = \mathbf{M}^{-1} \mathbf{J}(\mathbf{W})^t$ , and  $\mathbf{A} = \mathbf{M}^{-1}$ .

For the choice  $\mathbf{W}^t = \mathbf{M}_{\xi} \mathbf{J}_{\xi} \mathbf{M}^{-1}$ ,  $\mathbf{M}_{\xi}^{-1} = \mathbf{J}_{\xi} \mathbf{M}^{-1} \mathbf{J}_{\xi}^t$ , we get

$$\nabla_{\xi} A = - \left\langle \frac{d}{dt} \left( \mathbf{M}_{\xi} \frac{d\boldsymbol{\xi}}{dt} \right) \Big|_{\xi} \right\rangle. \quad (2.3.0.22)$$

This equation is much easier to implement numerically than Eq. 2.3.0.19. No second derivatives are involved. This is especially convenient since computing terms like  $\partial \mathbf{M}_{\xi} / \partial x_t$  can be quite tedious to implement.

## 2.4 $\lambda$ -dynamics

The coupling parameter  $\lambda$  is treated as a pseudo particle with fictitious mass  $m_\lambda$ . The extended Hamiltonian for the system with a coupling parameter in one dimension can be written as

$$H(\mathbf{R}, \lambda) = H_{Rxn}(\mathbf{R}, \lambda) + \frac{m_\lambda}{2} \dot{\lambda}^2 + U^*(\lambda), \quad (2.4.0.1)$$

where  $H_{Rxn}$  is a legitimate mapping provided that  $H_{Rxn}(\mathbf{R}, \lambda = 0)$  and  $H_{Rxn}(\mathbf{R}, \lambda = 1)$  correspond to the Hamiltonians for the reactant and product states respectively, and  $U^*(\lambda)$  is a restraint that limits the range of  $\lambda$ . Extension of this method to multiple coupling parameters  $\{\lambda_i\}$  is straightforward. The pseudo particles can be coupled to high temperature baths, so it can have strengthened ability to overcome the barrier. However, this might lead to energy transfer between the pseudo degrees of freedom to the configuration degrees of freedom. Therefore, the fictitious mass  $m_\lambda$  should be large enough to make this degree of freedom nearly adiabatic from the rest of the system.[14]  $\lambda$ -dynamics can also be coupled with metadynamics,[15] which will be introduced in Sec. 2.5.

## 2.5 Metadynamics

Metadynamics, vividly called flooding method, was first suggested by Laio and Parrinello in 2002.[16] Imagine you were standing in a valley and were surrounded by high mountains. In most of the time, you were just wandering near the minimum, because your kinetic energy was not enough to climb the mountains. Suddenly, you realized that you could use metadynamics as a magic to escape from the minimum. You started walking. After each step, you took a bottle of sand out of your miraculous pocket and put the sand under your feet. Then you were lifted up inch-by-inch, and the deposited sand piles discourage you from revisiting where you had visited. And you were finally raised up to the top of the mountain and at that moment you were able to climb over that mountain without much effort and fell into another valley. The magic of sand continued, and at last you smoothed the whole area. Because you kept recording where you had put the sand and how much sand you had put there. You drew the shape the piled sand according to the record and you flipped it. In this way, you got the exact shape of the original free energy landscape up to a constant.

Figure 2.3: A schematic representation of metadynamics. The free energy well is gradually filled up with small Gaussians, and a transition is facilitated.

The above texts are merely an informal explanation of metadynamics. Formally, metadynamics belongs to a class of methods in which sampling is facilitated by introducing additional bias potential to pre-selected degrees of freedom, which are often referred as collective variables (CVs). In metadynamics, the bias potential added to the Hamiltonian of the system is history-dependent, and is often written as a sum of Gaussians deposited during the simulation as

$$V_G(\mathbf{s}, t) = \int_0^t dt' \omega \exp \left( - \sum_{i=1}^d \frac{[\mathbf{s}_i(R) - \mathbf{s}_i(R(t'))]^2}{2\sigma_i^2} \right) \quad (2.5.0.1)$$

on a collective variable  $\mathbf{s}$  in  $d$ -dimension.  $\sigma$  and  $\omega$  are two parameters tuning the shape of the Gaussians, which can be time-dependent. Asymptotically,

$$V_G(\mathbf{s}, t \rightarrow \infty) = -G(\mathbf{s}) + C. \quad (2.5.0.2)$$

Recent improvement over the ordinary metadynamics on convergence issue, which is termed well-tempered metadynamics (WTMetaD), can be found in Ref. [17] and is reviewed in Ref. [18]. In this method, a gradually tempered Gaussian hill

$$V_n(\mathbf{s}) = V_{n-1}(\mathbf{s}) + G(\mathbf{s}, \mathbf{s}_n) \exp \left[ -\frac{1}{\gamma - 1} \beta V_{n-1}(\mathbf{s}_n) \right] \quad (2.5.0.3)$$

is accumulated, where  $V_0(\mathbf{s}) = 0$  and

$$G(\mathbf{s}, \mathbf{s}') = W \exp \left( -\|\mathbf{s} - \mathbf{s}'\|^2 \right) \quad (2.5.0.4)$$

with  $\|\mathbf{s} - \mathbf{s}'\|^2$  being a distance metric such as

$$\|\mathbf{s} - \mathbf{s}'\|^2 = \frac{1}{2} \sum_{i,j} (\mathbf{s}_i - \mathbf{s}'_i) \Sigma_{i,j}^{-1} (\mathbf{s}_j - \mathbf{s}'_j). \quad (2.5.0.5)$$

$\Sigma_{i,j}^{-1}$  is the inverse of the covariance matrix  $\Sigma_{i,j}$ , and the latter is normally diagonal  $\Sigma_{i,j} = \delta_{i,j} \sigma_i^2$ .  $W$  is the height of the Gaussian.  $G(\mathbf{s}, \mathbf{s}_n)$  is the biasing kernel centered on the current CV value  $\mathbf{s}_n$  and is scaled by  $\exp \left[ -\frac{1}{\gamma - 1} \beta V_{n-1}(\mathbf{s}_n) \right]$  when being accumulated. The scaling factor itself decreases as  $1/n$ , therefore the change of the biasing potential becomes smaller as the metadynamics simulation progresses.[19]

Practically, the update of the biasing potential is performed every  $N_G$  steps. Between any two adjacent updates, the system evolves under the action of the biasing potential  $V_n(\mathbf{s}(\mathbf{R}))$ . After the  $n$ th update, the biasing potential is

$$V(\mathbf{s}, t) = \sum_{k=1}^n W \exp \left( -\|\mathbf{s} - \mathbf{s}_k\|^2 \right) \exp \left[ -\frac{1}{\gamma - 1} \beta V_{k-1}(\mathbf{s}_k) \right]. \quad (2.5.0.6)$$

The factor  $(\gamma - 1)\beta^{-1}$  is sometimes referred to as  $k_B \Delta T$ .

The remarkable feature of this stochastic update of the biasing potential is that the evolution of the bias can be described asymptotically by an ordinary differential equation (ODE), which after some manipulations reads

$$\frac{dV(\mathbf{s}, t)}{dt} = \int d\mathbf{s}' G(\mathbf{s}, \mathbf{s}') \exp \left[ -\frac{1}{\gamma - 1} \beta V(\mathbf{s}', t) \right] P_V(\mathbf{s}', t), \quad (2.5.0.7)$$

where

$$P_V(\mathbf{s}, t) = \frac{e^{-\beta[F(\mathbf{s}) + V(\mathbf{s}, t)]}}{\int d\mathbf{s}' e^{-\beta[F(\mathbf{s}') + V(\mathbf{s}', t)]}}. \quad (2.5.0.8)$$

For any  $G(\mathbf{s}, \mathbf{s}')$ , this ODE has the asymptotic solution

$$V(\mathbf{s}, t) = - \left(1 - \frac{1}{\gamma}\right) F(\mathbf{s}) + c(t), \quad (2.5.0.9)$$

where

$$c(t) = \frac{1}{\beta} \log \frac{\int d\mathbf{s} e^{-\beta F(\mathbf{s})}}{\int d\mathbf{s} e^{-\beta[F(\mathbf{s})+V(\mathbf{s},t)]}} \quad (2.5.0.10)$$

is independent of  $\mathbf{s}$ . Metadynamics thus converges to the desired result. Two interesting consequences arise.

First, it can be shown that a time-dependent estimator for  $F(\mathbf{s})$  is given by

$$F(\mathbf{s}) = - \left(\frac{\gamma}{\gamma-1}\right) V(\mathbf{s}, t) + \frac{1}{\beta} \log \int d\mathbf{s} \exp \left[ \frac{\gamma}{\gamma-1} \beta V(\mathbf{s}, t) \right]. \quad (2.5.0.11)$$

Taking this equation into Eq. 2.5.0.10, one obtains

$$c(t) = \frac{1}{\beta} \log \frac{\int d\mathbf{s} \exp \left[ \frac{\gamma}{\gamma-1} \beta V(\mathbf{s}, t) \right]}{\int d\mathbf{s} \exp \left[ \frac{1}{\gamma-1} \beta V(\mathbf{s}, t) \right]}. \quad (2.5.0.12)$$

Second, it offers a practical way of calculating the expectation value of any  $\mathbf{R}$ -dependent function  $O(\mathbf{R})$  as the simulation proceeds. The idea is that at time  $t$  the biased probability distribution for  $\mathbf{R}$  is given by

$$P_V(\mathbf{R}, t) = \frac{e^{-\beta[U(\mathbf{R})+V(\mathbf{s}(\mathbf{R}),t)]}}{\int d\mathbf{R} e^{-\beta[U(\mathbf{R})+V(\mathbf{s}(\mathbf{R}),t)]}}, \quad (2.5.0.13)$$

which can be rewritten as

$$P_V(\mathbf{R}, t) = P(\mathbf{R}) e^{-\beta[V(\mathbf{s}(\mathbf{R}),t)-c(t)]}, \quad (2.5.0.14)$$

where  $P(\mathbf{R})$  is the unbiased Boltzmann distribution, and  $e^{\beta[V(\mathbf{s}(\mathbf{R}),t)-c(t)]}$  is the time-dependent unbiasing factor. Straightforwardly, the average of  $O(\mathbf{R})$  over the unbiased ensemble can be calculated from the metadynamics trajectory as

$$\langle O(\mathbf{R}) \rangle = \left\langle O(\mathbf{R}) e^{\beta[V(\mathbf{s}(\mathbf{R}),t)-c(t)]} \right\rangle_V. \quad (2.5.0.15)$$

This reweighting can be used to obtain the FES for some set of CVs  $\mathbf{s}'$  either biased or unbiased by setting  $O(\mathbf{R}) = \delta[\mathbf{s}' - \mathbf{s}'(\mathbf{R})]$ . It is also useful if one chooses  $\mathbf{s}'$  as the biased degree of freedom  $\mathbf{s}$  and obtain the FES. Disagreement between the FESs obtained directly from the bias potential and through reweighting is a clear sign that the metadynamics simulation has not converged.

Metadynamics has been implemented in PLUMED ([https://plumed.github.io/doc-v2.3/user-doc/html/\\_metadyn.html](https://plumed.github.io/doc-v2.3/user-doc/html/_metadyn.html)), which can work with major molecular dynamics packages.

## 2.6 Orthogonal Space Random Walk

The orthogonal space random walk (OSRW) was developed by Yang in 2008.[20] Phase space sampling is always hindered by free energy barriers. As shown above, several methods have been proposed to accelerate the transition between two states separated by a large free energy barrier, via alchemical process or enhanced conformational switching. In alchemical process, we define a coupling parameter  $\lambda$ . Similarly, in conformational switching we define a reaction coordinate  $\mathbf{S}$ . Essentially, these two methods are the same, because the coupling parameter  $\lambda$  can be regarded as a coordinate for extended dynamics. Without loss of generality, we can write the free energy difference with the order parameter  $\xi = \xi_i$  and  $\xi = \xi_f$  as

$$\Delta G(\xi_i \rightarrow \xi_f) = \int_{\xi_i}^{\xi_f} \left. \frac{\partial G}{\partial \xi} \right|_{\xi'} d\xi' = \int_{\xi_i}^{\xi_f} \left\langle \frac{\partial U}{\partial \xi} - \beta^{-1} \frac{\partial \ln |J|}{\partial \xi} \right\rangle_{\xi'} d\xi', \quad (2.6.0.1)$$

where  $J$  is the Jacobian term corresponding to the coordinate transformation between the Cartesian coordinates and the reaction coordinates, and  $\frac{\partial U}{\partial \xi} - RT \frac{\partial \ln |J|}{\partial \xi}$  can be regarded as the generalized force  $F_\xi$  on  $\xi$ . Because the transformation from  $\xi = \xi_i$  to  $\xi = \xi_f$  is slow, we can either constrain or restrain the system to a series of  $\xi'$ . Unfortunately, albeit the acceleration along the reaction coordinate, the relaxation of the other degrees of freedom is usually hindered by some “hidden barriers” and is not able to catch up with the alternation of the reaction coordinate. This is called “Hamiltonian lagging” as identified by Kollman et al.[21] Therefore, acceleration of the space orthogonal to the reaction coordinate is equally important as the acceleration of the reaction coordinate.

Orthogonal space random walk is one of the approaches that can deal with this difficulty. In this method, all the coordinates perpendicular to the reaction coordinate are grouped together into  $F_\xi$ . A small two dimensional biasing potential  $G(\xi, F_\xi)$ , instead of a one-dimensional one as in metadynamics (see Sec. 2.5), is added to the Hamiltonian of the system recursively, which has a functional form like

$$h \exp \left( -\frac{|\xi - \xi(t_i)|^2}{2w_1^2} \right) \exp \left( -\frac{|F_\xi - F_\xi(t_i)|^2}{2w_2^2} \right). \quad (2.6.0.2)$$

The overall biasing potential

$$G(\xi, F_\xi) = \sum_{t_i} h \exp \left( -\frac{|\xi - \xi(t_i)|^2}{2w_1^2} \right) \exp \left( -\frac{|F_\xi - F_\xi(t_i)|^2}{2w_2^2} \right). \quad (2.6.0.3)$$

will eventually flatten the underlying free energy surface along the orthogonal space. Application of this biasing potential to conformational free energy calculations is straightforward, while for alchemical free energy calculations

it can be realized by  $\lambda$ -dynamics developed by Charlie Brooks.[22] Similar to metadynamics, the free energy profile along the two-dimensional reaction coordinates  $[\xi(t_i), F_\xi]$  can be estimated as  $-G(\xi, F_\xi) + C$ , where  $C$  is an irrelevant constant. Correspondingly, the generalized force distribution at  $\xi'$  should be proportional to  $\exp[\beta G(\xi', F_{\xi'})]$ , and the free-energy derivative can be obtained via

$$\left. \frac{\partial G}{\partial \xi} \right|_{\xi'} = \langle F_\xi \rangle_{\xi'} = \frac{\sum F_\xi \exp[\beta G(\xi, F_\xi)] \delta(\xi - \xi')}{\sum \exp[\beta G(\xi, F_\xi)] \delta(\xi - \xi')}, \quad (2.6.0.4)$$

which can be fed into the thermodynamic integration formula to obtain the free energy change from  $\xi = \xi_i$  to any target state with the order parameter  $\xi$  as the following

$$\Delta G(\xi) = \int_{\xi_i}^{\xi} \left. \frac{\partial G}{\partial \xi} \right|_{\xi'} d\xi'. \quad (2.6.0.5)$$

## 2.7 Enveloping Distribution Sampling

Enveloping distribution sampling method was first proposed by Christ and van Gunsteren in 2007.[23] When calculating the free energy difference between states  $A$  and  $B$ ,

$$\Delta G_{BA} = G_B - G_A = -\beta^{-1} \ln \frac{Q_B}{Q_A}, \quad (2.7.0.1)$$

we may encounter convergence difficulty if the important spaces of these two states are well separated, shown as black lines in Fig. 2.4. Simulation under the Hamiltonian of state  $A$  can hardly cover the important region of Hamiltonian  $B$ , and then the free energy of state  $B$  will be significantly overestimated.

Figure 2.4: The configuration distributions under two Hamiltonians have no visible overlap as shown by solid black curves. A reference state (shown as the red curve) that has remarkable overlap with both states can be introduced to accelerate the convergence of the free energy calculations using, for instance, TP.

A simple solution to this difficulty is “overlap sampling”, in which a reference state that can cover the important regions of both Hamiltonians  $A$  and  $B$  is introduced. We then carry out a simulation for the reference state and the free energy difference between state  $A$  and  $B$  can be calculated as

$$\Delta G_{BA} = \Delta G_{BR} - \Delta G_{AR} = -\beta^{-1} \ln \frac{\langle e^{-\beta(H_B - H_R)} \rangle_R}{\langle e^{-\beta(H_A - H_R)} \rangle_R}, \quad (2.7.0.2)$$

which is a combination of two thermodynamic perturbation calculations from the reference state to the target states.

However, building the Hamiltonian of the reference state is not trivial. Without knowledge of the Hamiltonians for state  $A$  and state  $B$ , we cannot generate an effective Hamiltonian, especially in a high dimensional space. Enveloping distribution sampling method provides a natural way to generate the Hamiltonian for the reference state with simply mixing the Hamiltonians of state  $A$  and state  $B$  in the following way

$$H_R(\mathbf{r}) = -(s\beta)^{-1} \ln \left( e^{-s\beta H_A(\mathbf{r})} + e^{-s\beta H_B(\mathbf{r})} \right), \quad (2.7.0.3)$$

where  $s$  is a scale factor that modulates the mixing[24] as shown in Fig. 2.5. Increasing  $s$  lowers the barrier height separating the two minima in the mixed potential, thereby enhances the transition. Straightforwardly, you may come to the idea that running Hamiltonian-REMD with different  $s$  can remarkably increase the efficiency. If you take a close look at Eq. 2.7.0.3, you will find that  $s$  appears always with  $\beta$ . In other words, changing  $s$  is equivalent to changing the temperature for the simulation. This is one interesting case where H-REMD and T-REMD are coincident with each other.

Figure 2.5: State A and state B have only negligible overlap at high energy regions. The reference state generated by the mixing of state A and state B is characterized by  $s$ . Increasing  $s$  may lower the barrier between the dominant wells.

The force is also a mixing quantity from two Hamiltonians as

$$\mathbf{F}_R^i = -\frac{\partial H_R}{\partial \mathbf{r}^i} = \frac{e^{-s\beta H_A(\mathbf{r})}}{e^{-s\beta H_A(\mathbf{r})} + e^{-s\beta H_B(\mathbf{r})}} \left( -\frac{\partial H_A(\mathbf{r})}{\partial \mathbf{r}^i} \right) + \frac{e^{-s\beta H_B(\mathbf{r})}}{e^{-s\beta H_A(\mathbf{r})} + e^{-s\beta H_B(\mathbf{r})}} \left( -\frac{\partial H_B(\mathbf{r})}{\partial \mathbf{r}^i} \right). \quad (2.7.0.4)$$

### 3.1 Rigorous Methods

#### 3.1.1 Thermodynamic Perturbation

Thermodynamic Perturbation (TP), also known as Free Energy Perturbation (FEP), exponential average, or Zwanzig equation was developed by Zwanzig,[25] and Landau and Lifshitz, independently, and probably by Peierls[26].

A reference system containing  $N$ -particles can be described by Hamiltonian  $H_0(\mathbf{x}, \mathbf{p}_x)$ , which is a function of  $3N$  Cartesian coordinates,  $\mathbf{x}$ , and their conjugated momenta,  $\mathbf{p}_x$ . Similarly, the target system can be described by Hamiltonian  $H_1(\mathbf{x}, \mathbf{p}_x)$ . These two systems are related by

$$H_1(\mathbf{x}, \mathbf{p}_x) = H_0(\mathbf{x}, \mathbf{p}_x) + \Delta H(\mathbf{x}, \mathbf{p}_x) \quad (3.1.1.1)$$

The Helmholtz free energy difference between the target and the reference systems,  $\Delta A$ , can be given in terms of the ratio of the corresponding partition functions,  $Q_1$  and  $Q_0$ :

$$\Delta A = -\frac{1}{\beta} \ln \frac{Q_1}{Q_0}, \quad (3.1.1.2)$$

where  $\beta = (k_B T)^{-1}$ , and

$$Q_i = \frac{1}{h^{3N} N!} \iint \exp[-\beta H_i(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x. \quad (3.1.1.3)$$

Taking Eq. 3.1.1.3 into Eq. 3.1.1.2, we obtain

$$\Delta A = -\frac{1}{\beta} \ln \frac{\iint \exp[-\beta H_1(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x}{\iint \exp[-\beta H_0(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x} \quad (3.1.1.4)$$

$$= -\frac{1}{\beta} \ln \frac{\iint \exp[-\beta \Delta H(\mathbf{x}, \mathbf{p}_x)] \exp[-\beta H_0(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x}{\iint \exp[-\beta H_0(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x}, \quad (3.1.1.5)$$

The probability density function of finding the reference system in a state defined by positions  $\mathbf{x}$  and momenta  $\mathbf{p}_x$  is

$$P_0(\mathbf{x}, \mathbf{p}_x) = \frac{\exp[-\beta H_0(\mathbf{x}, \mathbf{p}_x)]}{\iint \exp[-\beta H_0(\mathbf{x}, \mathbf{p}_x)] d\mathbf{x} d\mathbf{p}_x} \quad (3.1.1.6)$$

If the probability density function is used, Eq. 3.1.1.5 becomes

$$\Delta A = -\frac{1}{\beta} \ln \iint \exp[-\beta \Delta H(\mathbf{x}, \mathbf{p}_x)] P_0(\mathbf{x}, \mathbf{p}_x) d\mathbf{x} d\mathbf{p}_x, \quad (3.1.1.7)$$

or, equivalently,

$$\Delta A = -\frac{1}{\beta} \ln \langle \exp[-\beta \Delta H(\mathbf{x}, \mathbf{p}_x)] \rangle_0, \quad (3.1.1.8)$$

Here,  $\langle \cdots \rangle_0$  denotes an ensemble average over configurations sampled from the reference state. Equation 3.1.1.8 is the basic equation of TP. It states that  $\Delta A$  can be estimated by sampling only equilibrium configurations of the reference state.

Note that integration over the kinetic term in the partition function, Eq. 3.1.1.3, can be carried out analytically. Thus, it cancels out in Eq. 3.1.1.2, and Eq. 3.1.1.8 becomes

$$\Delta A_f = -\frac{1}{\beta} \ln \langle \exp(-\beta \Delta U) \rangle_0, \quad (3.1.1.9)$$

where  $\Delta U$  is the difference in the potential energy between the target and the reference states. The subscript  $f$  is an indication of a forward ( $0 \rightarrow 1$ ) TP calculation. The integration implied by the statistical average is now carried out over particle coordinates only. The variance of  $\Delta A$  is

$$\delta^2 \Delta A_f = \frac{1}{N_0 \beta^2} \left( \frac{\langle (\exp(-\beta \Delta U))^2 \rangle_0}{(\langle \exp(-\beta \Delta U) \rangle_0)^2} - 1 \right). \quad (3.1.1.10)$$

If we exchange the reference and the target systems, and repeat the same derivation, using the same convention for  $\Delta A$  and  $\Delta U$  as before, we have a backward TP expression for the free energy difference

$$\Delta A_b = \frac{1}{\beta} \ln \langle \exp(\beta \Delta U) \rangle_1, \quad (3.1.1.11)$$

and the variance is

$$\delta^2 \Delta A_b = \frac{1}{N_1 \beta^2} \left( \frac{\langle (\exp(\beta \Delta U))^2 \rangle_1}{(\langle \exp(\beta \Delta U) \rangle_1)^2} - 1 \right). \quad (3.1.1.12)$$

Although expressions Eq. 3.1.1.9 and Eq. 3.1.1.11 are formally equivalent, their convergence properties may be quite different. This means that there is a preferred direction to carry out the required transformation between the two states. One should start the perturbation from the state having larger important region in phase space. In other words, the reference system should be that with higher entropy, and the transformation should proceed in the direction in which the entropy decreases. If we have the free energy differences from both the forward and backward TP calculations, we can compute the “best estimate” of  $\Delta A$  as

$$\Delta A = \frac{(\delta^2 \Delta A_f)^{-1} \Delta A_f + (\delta^2 \Delta A_b)^{-1} \Delta A_b}{(\delta^2 \Delta A_f)^{-1} + (\delta^2 \Delta A_b)^{-1}}, \quad (3.1.1.13)$$

with variance

$$\delta^2 \Delta A = \frac{1}{(\delta^2 \Delta A_f)^{-1} + (\delta^2 \Delta A_b)^{-1}}. \quad (3.1.1.14)$$

Equation 3.1.1.9 and Eq. 3.1.1.11, are formally exact for any perturbation. However, this does not mean that they can always be successfully applied. Since  $\Delta A$  is calculated as the average over a quantity that depends only on  $\Delta U$ , this average can be computed over probability distribution  $P_0(\Delta U)$  instead of  $P_0(\mathbf{x}, \mathbf{p}_x)$ . Then,  $\Delta A$  in Eq. 3.1.1.7 can be expressed as a one-dimensional integral over energy difference

$$\Delta A = -\frac{1}{\beta} \ln \int \exp(-\beta \Delta U) P_0(\Delta U) d\Delta U, \quad (3.1.1.15)$$

If  $U_0$  and  $U_1$  were functions of a sufficient number of identically distributed random variable,  $\Delta U$  would follow a Gaussian distribution, which is a consequence of the central limit theorem. In practice, the probability distribution  $P_0(\Delta U)$  deviates somewhat from an ideal Gaussian case, but still has a “Gaussian-like” shape. This indicates that the value of the integral in Eq. 3.1.1.15 depends on the low-energy tail of the distribution.

Even though  $P_0(\Delta U)$  is only rarely an exact Gaussian, it is instructive to consider this case in more detail.

If we substitute

$$P_0(\Delta U) = \frac{1}{\sqrt{2\pi}\sigma} \exp \left[ -\frac{(\Delta U - \langle \Delta U \rangle_0)^2}{2\sigma^2} \right] \quad (3.1.1.16)$$

where

$$\sigma^2 = \langle \Delta U^2 \rangle_0 - \langle \Delta U \rangle_0^2 \quad (3.1.1.17)$$

Figure 3.1:  $P_0(\Delta U)$ , the Boltzmann factor  $\exp(-\beta\Delta U)$  and their product, which is the integrand in Eq. 3.1.1.15. The low- $\Delta U$  tail of the integrand is poorly sampled with  $P_0(\Delta U)$  and, therefore, is known with low statistical accuracy. However, it provides an important contribution to the integral.

to Eq. 3.1.1.15, we obtain

$$\exp(-\beta\Delta A) = \frac{C}{\sqrt{2\pi}\sigma} \int \exp\left[-\frac{(\Delta U - \langle\Delta U\rangle_0 - \beta\sigma^2)^2}{2\sigma^2}\right] d\Delta U \quad (3.1.1.18)$$

Here,  $C$  is independent of  $\Delta U$

$$C = \exp\left[-\beta\left(\langle\Delta U\rangle_0 - \frac{1}{2}\beta\sigma^2\right)\right] \quad (3.1.1.19)$$

If  $P_0(\Delta U)$  is Gaussian, the integral in Eq. 3.1.1.18 can be evaluated analytically using cumulant expansion (see appendix D)

$$\Delta A = \langle\Delta U\rangle_0 - \frac{1}{2}\beta\sigma^2. \quad (3.1.1.20)$$

If the distribution of  $\Delta U$  deviates from Gaussian, there will be extra terms measuring the skewness of Gaussian. With the leading term,  $\Delta A$  becomes

$$\Delta A = \langle\Delta U\rangle_0 - \frac{1}{2}\beta\sigma^2 + \frac{\beta^2}{6} \left( \langle\Delta U^3\rangle_0 - 3\langle\Delta U^2\rangle_0\langle\Delta U\rangle_0 + 2\langle\Delta U\rangle_0^3 \right). \quad (3.1.1.21)$$

### 3.1.2 Thermodynamic Integration

Thermodynamic Integration (TI) method was proposed by Kirkwood.[27]. If the free energy,  $A$ , is a continuous function of  $\lambda$ , the free energy difference between two states corresponding to  $\lambda = 0$  and  $\lambda = 1$  can be computed via

$$\Delta A = \int_0^1 \frac{\partial A(\lambda)}{\partial \lambda} d\lambda. \quad (3.1.2.1)$$

With

$$A(\lambda) = -\beta^{-1} \ln Q(\lambda), \quad (3.1.2.2)$$

the partial derivative can be expressed as

$$\begin{aligned} \frac{\partial A(\lambda)}{\partial \lambda} &= -\beta^{-1} \left[ \frac{\partial \ln Q(\lambda)}{\partial \lambda} \right] \\ &= -\frac{\beta^{-1}}{Q(\lambda)} \frac{\partial Q(\lambda)}{\partial \lambda}. \end{aligned} \quad (3.1.2.3)$$

From the definition of  $Q$

$$Q_{NVT}(\lambda) = \frac{1}{h^{3N} N!} \iint \exp[-\beta H(\mathbf{x}, \mathbf{p}_x, \lambda)] d\mathbf{x} d\mathbf{p}_x, \quad (3.1.2.4)$$

we have

$$\begin{aligned} \frac{\partial Q(\lambda)}{\partial \lambda} &= \frac{1}{h^{3N} N!} \iint \frac{\partial}{\partial \lambda} \exp[-\beta H(\mathbf{x}, \mathbf{p}_x, \lambda)] d\mathbf{x} d\mathbf{p}_x \\ &= -\frac{\beta}{h^{3N} N!} \iint \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \exp[-\beta H(\mathbf{x}, \mathbf{p}_x, \lambda)] d\mathbf{x} d\mathbf{p}_x. \end{aligned} \quad (3.1.2.5)$$

Substituting back into the expression for  $\partial A/\partial \lambda$  yields

$$\begin{aligned} \frac{\partial A(\lambda)}{\partial \lambda} &= \frac{1}{h^{3N} N!} \frac{1}{Q(\lambda)} \iint \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \exp[-\beta H(\mathbf{x}, \mathbf{p}_x, \lambda)] d\mathbf{x} d\mathbf{p}_x, \\ &= \frac{1}{h^{3N} N!} \iint \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \cdot \frac{\exp[-\beta H(\mathbf{x}, \mathbf{p}_x, \lambda)]}{Q(\lambda)} d\mathbf{x} d\mathbf{p}_x, \\ &= \left\langle \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \right\rangle_\lambda \end{aligned} \quad (3.1.2.6)$$

Thus, the basic TI formula is

$$\Delta A = \int_{\lambda=0}^{\lambda=1} \left\langle \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \right\rangle_\lambda d\lambda \quad (3.1.2.7)$$

where  $\langle \cdots \rangle_\lambda$  corresponds to the ensemble average obtained using the Hamiltonian  $H(\lambda)$ . In practice, the ensemble of configurations can be obtained by molecular dynamics or Monte Carlo simulations. It is common practice in free energy calculations to use the coupling parameter  $\lambda$  for defining the

transformation from the initial state  $A$  with Hamiltonian  $H_A$  to the final state  $B$  with Hamiltonian  $H_B$ . The simplest coupling is linear transformation as

$$H(\lambda) = (1 - \lambda)H_A + \lambda H_B \quad (3.1.2.8)$$

The accuracy of TI integral formula depends on the exactness of the numerical integration method.[28] Practically, the integrand in Eq. 3.1.2.7 needs to be evaluated over a number of discrete points  $\lambda_i$ , and then be summed up to give the free energy difference between  $\lambda = 0$  and 1, for instance via the trapezoidal rule

$$\Delta A = \sum_{i=0}^{N-1} \frac{1}{2} \left( \left\langle \frac{\partial H(\lambda)}{\partial \lambda} \right\rangle_{\lambda_i} + \left\langle \frac{\partial H(\lambda)}{\partial \lambda} \right\rangle_{\lambda_{i+1}} \right) (\lambda_{i+1} - \lambda_i). \quad (3.1.2.9)$$

A finite number of  $\lambda_i$  values between 0 and 1 are chosen and for each of them a complete molecular dynamics simulation is carried out resulting in an ensemble of configurations generated with  $H(\lambda_i)$ . The ensemble average of the derivative of the Hamiltonian with respect to  $\lambda$  is then calculated for each  $\lambda_i$ .

In addition to summation method, the simplest numerical integration is to evaluate the integrand at the midpoint:

$$\Delta A \simeq \left\langle \frac{\partial H(\lambda)}{\partial \lambda} \right\rangle_{\lambda=\frac{1}{2}} \quad (3.1.2.10)$$

This might be a good first thing to do to get some impression of what is going on, but is only accurate for very smooth or small changes.

### 3.1.3 Bennett Acceptance Ratio

*“The thing that differentiates scientists is purely an artistic ability to discern what is a good idea, what is a beautiful idea, what is worth spending time on, and most importantly, what is a problem that is sufficiently interesting, yet sufficiently difficult, that is hasn’t yet been solved, but the time for solving it has come now.”*

– Professor Savas Dimopoulos, Stanford University

Bennett acceptance ratio was developed by Bennett in 1976,[29] and was re-discovered by Crooks[30] for Markovian and balanced dynamics and by Shirts et al[31] using maximum likelihood over 20 years later. The Metropolis function is defined as

$$M(x) = \min\{1, \exp(-x)\}, \quad (3.1.3.1)$$

which has the property

$$M(x)/M(-x) = \exp(-x). \quad (3.1.3.2)$$

If we make a trial move that keeps the same configuration  $(q_1, \dots, q_N)$  but switches the potential function from  $U_0$  to  $U_1$  or vice-versa, the acceptance probabilities for such a pair of trial moves must satisfy the detailed balance

$$M(U_1 - U_0) \exp(-U_0) = M(U_0 - U_1) \exp(-U_1). \quad (3.1.3.3)$$

Integrating this identity over all of configuration space and multiplying by the trivial factors  $Q_0/Q_0$  and  $Q_1/Q_1$ , one obtains:

$$Q_0 \frac{\int M(U_1 - U_0) \exp(-U_0) d\mathbf{q}}{Q_0} = Q_1 \frac{\int M(U_0 - U_1) \exp(-U_1) d\mathbf{q}}{Q_1}, \quad (3.1.3.4)$$

or simply

$$\frac{Q_0}{Q_1} = \frac{\langle M(U_0 - U_1) \rangle_1}{\langle M(U_1 - U_0) \rangle_0}. \quad (3.1.3.5)$$

The physical meaning of this formula is that a Monte Carlo calculation that includes potential-switching trial moves would distribute configurations between  $U_1$  and  $U_0$  in the ratio of their configurational integrals.

A formula more general than Eq. 3.1.3.5 can be written as

$$\frac{Q_0}{Q_1} = \frac{Q_0 \int W \exp(-U_0 - U_1) d\mathbf{q}}{Q_1 \int W \exp(-U_1 - U_0) d\mathbf{q}} = \frac{\langle W \exp(-U_0) \rangle_1}{\langle W \exp(-U_1) \rangle_0}, \quad (3.1.3.6)$$

where  $W$  is an arbitrary weighting function.

Optimization of the free energy estimate is most easily carried out in the limit of large sample sizes. Let the available data consist of  $n_0$  statistically independent configurations from the  $U_0$  ensemble and  $n_1$  from the  $U_1$  ensemble, and let the data be used in Eq. 3.1.3.6 to obtain a finite-sample estimate of the reduced free energy difference  $\Delta A = A_1 - A_0 = \ln(Q_0/Q_1)$ . Using the error propagation law of uncorrelated variables ( $\text{covar}(x_1, x_2) = 0$ ), [32]

$$\delta^2[y(x_1, x_2)] = \left(\frac{\partial y}{\partial x_1}\right)^2 \delta^2(x_1) + \left(\frac{\partial y}{\partial x_2}\right)^2 \delta^2(x_2). \quad (3.1.3.7)$$

Thus we have the variance of  $\Delta A$

$$\begin{aligned} \delta^2(\Delta A) &= \left(\frac{\partial \Delta A}{\partial Q_0}\right)^2 \delta^2 Q_0 + \left(\frac{\partial \Delta A}{\partial Q_1}\right)^2 \delta^2 Q_1 \\ &= \left(\frac{1}{Q_0}\right)^2 \delta^2 Q_0 + \left(-\frac{1}{Q_1}\right)^2 \delta^2 Q_1 \\ &= \left(\frac{1}{Q_0}\right)^2 \delta^2 Q_0 + \left(\frac{1}{Q_1}\right)^2 \delta^2 Q_1. \end{aligned} \quad (3.1.3.8)$$

With the definition of variance  $\delta^2 X = \langle X^2 \rangle - \langle X \rangle^2$ , we have

$$\begin{aligned} \delta^2 Q_0 &= \delta^2 \langle W \exp(-U_0) \rangle_1 \\ &= \delta^2 \left( \frac{1}{n_1} \sum_{i=1}^{n_1} W_i \exp(-U_0(i)) \right) \\ &= \sum_{i=1}^{n_1} \left( \frac{1}{n_1} \right)^2 \delta^2 (W_i \exp(-U_0(i))) \\ &= \frac{1}{n_1} \delta^2 (W_i \exp(-U_0(i))) \\ &= \frac{1}{n_1} \left\{ \langle [W \exp(-U_0)]^2 \rangle_1 - [\langle W \exp(-U_0) \rangle_1]^2 \right\} \\ &= \frac{1}{n_1} \left\{ \langle W^2 \exp(-2U_0) \rangle_1 - [\langle W \exp(-U_0) \rangle_1]^2 \right\}, \end{aligned} \quad (3.1.3.9)$$

which shows that the variance of the mean of the samples equals to the variance of the samples divided by the number of samples.

With sufficiently large sample sizes, the error of this estimate will be nearly Gaussian, and its expected square is exactly the variance of  $\Delta A$

$$\begin{aligned} &\delta^2(\Delta A_{est} - \Delta A) \\ &\approx \frac{\langle W^2 \exp(-2U_1) \rangle_0}{n_0 [\langle W \exp(-U_1) \rangle_0]^2} + \frac{\langle W^2 \exp(-2U_0) \rangle_1}{n_1 [\langle W \exp(-U_0) \rangle_1]^2} - \frac{1}{n_0} - \frac{1}{n_1} \\ &= \frac{\int [(Q_0/n_0) \exp(-U_1) + (Q_1/n_1) \exp(-U_0)] W^2 \exp(-U_0 - U_1) d\mathbf{q}}{[\int W \exp(-U_0 - U_1) d\mathbf{q}]^2} \\ &\quad - \frac{1}{n_0} - \frac{1}{n_1}. \end{aligned} \quad (3.1.3.10)$$

To minimize it with respect to  $W$ , we have

$$W = \text{const} \times \left( \frac{Q_0}{n_0} \exp(-U_1) + \frac{Q_1}{n_1} \exp(-U_0) \right)^{-1}. \quad (3.1.3.11)$$

Substituting this into Eq. 3.1.3.6 yields

$$\frac{Q_0}{Q_1} = \frac{\langle f(U_0 - U_1 + C) \rangle_1}{\langle f(U_1 - U_0 - C) \rangle_0} \exp(+C), \quad (3.1.3.12)$$

where

$$C = \ln \frac{Q_0 n_1}{Q_1 n_0}, \quad (3.1.3.13)$$

and  $f$  denotes the Fermi function

$$f(x) = \frac{1}{1 + \exp(+x)}. \quad (3.1.3.14)$$

It can also be expressed as[31]

$$n_1 \langle f(U_0 - U_1 + C) \rangle_1 = n_0 \langle f(U_1 - U_0 - C) \rangle_0. \quad (3.1.3.15)$$

It should be noted that Eq. 3.1.3.12 is true for any  $C$ , which is actually a shift for one of the potential function. But the particular value specified in Eq. 3.1.3.13 minimizes the expected square error given the finite numbers ( $n_0$  and  $n_1$ ) of samples.

The variance of  $\Delta A$  can be obtained by substituting Eq. 3.1.3.11 into Eq. 3.1.3.10, and is

$$\begin{aligned} \delta^2 \Delta A &= \frac{\langle f^2(U_1 - U_0 - C) \rangle_0}{n_0 \langle f(U_1 - U_0 - C) \rangle_0^2} + \frac{\langle f^2(U_0 - U_1 + C) \rangle_1}{n_1 \langle f(U_0 - U_1 + C) \rangle_1^2} - \frac{1}{n_0} - \frac{1}{n_1} \\ &= \left( \int \frac{n_0 n_1 \rho_0 \rho_1}{n_0 \rho_0 + n_1 \rho_1} d\mathbf{q} \right)^{-1} - \frac{n_0 + n_1}{n_0 n_1}, \end{aligned} \quad (3.1.3.16)$$

in which  $\rho_i = \exp(-U_i)/Q_i$  is the probability.

It is worth emphasizing that Bennett acceptance ratio is asymptotically unbiased, and no other asymptotically unbiased estimator has lower asymptotic mean-squared error. However, it is not clear whether its behavior is always better than other estimators with finite sample sizes.

### 3.1.4 Weighted Histogram Analysis Method

The weighted histogram analysis method is a generalization of the histogram method developed by Ferrenberg and Swendsen.[33]

#### Weighted Histogram Analysis Method for Parallel Tempering

The following derivation quite follows Ref. [34]. One of the central quantities in statistical mechanics is configurational integral  $Z$ , which in textbook is often written as

$$Z = \int \exp(-\beta U(\mathbf{R})) d\mathbf{R}. \quad (3.1.4.1)$$

This is an integral in coordinate space. It also can be written as an integral in energy space

$$Z = \int \Omega(U) \exp(-\beta U) dU, \quad (3.1.4.2)$$

where  $\Omega(U)$  is density of states and  $\Omega(U)\Delta U$  is the number of states in the region  $U - \Delta U/2 < U < U + \Delta U/2$ . Accordingly, the statistical expectation of an operator  $\mathbf{A}$  can be calculated by

$$\langle \mathbf{A} \rangle = \frac{\int \mathbf{A}(U) \Omega(U) \exp(-\beta U) dU}{\int \Omega(U) \exp(-\beta U) dU}, \quad (3.1.4.3)$$

where

$$\mathbf{A}(U') = \frac{\int \delta(U(\mathbf{R}) - U') \mathbf{A}(\mathbf{R}) d\mathbf{R}}{\int \delta(U(\mathbf{R}) - U') d\mathbf{R}}, \quad (3.1.4.4)$$

is the average of  $\mathbf{A}$  over all the samples with an energy  $U'$ . Therefore, the core objective is to calculate  $\Omega(U)$ .

Suppose we have one trajectory with  $N$  snapshots denoted as  $\{\mathbf{R}_n\}$ . We then discretize the energy space into  $M$  bins with width  $\Delta U$ , and count the number of snapshots into each bin. For convenience, we define  $\psi_m(U)$  as

$$\psi_m(U) = \begin{cases} 1 & \text{if } U \in [U_m - \Delta U/2, U_m + \Delta U/2) \\ 0 & \text{otherwise} \end{cases} \quad (3.1.4.5)$$

Then the histogram for the  $m$ th energy bin is

$$H_m = \sum_{n=1}^N \psi_m(U(\mathbf{R}_n)) = N \cdot \frac{1}{N} \sum_{n=1}^N \psi_m(U(\mathbf{R}_n)) = N \cdot \langle \psi_m \rangle, \quad (3.1.4.6)$$

with variances (see Appendix A)

$$\begin{aligned} \delta^2 H_m &= N^2 \delta^2(\langle \psi_m \rangle) \\ &= g_m N \left( \langle \psi_m^2 \rangle - \langle \psi_m \rangle^2 \right) \\ &= g_m N \left( \langle \psi_m \rangle - \langle \psi_m \rangle^2 \right) \\ &= g_m H_m \left( 1 - \frac{H_m}{N} \right). \end{aligned} \quad (3.1.4.7)$$

Figure 3.2: A sample histogram in 2D space, for instance potential energy and a reaction coordinate  $\xi$ .

A sample histogram in 2D space is shown in Fig. 3.2.

The ratio of the histogram  $H_m$  to the total number of snapshots  $N$  divided by the bin width  $\Delta U$  can be approximately taken as the probability of states in this bin, i.e.,

$$\frac{\Omega_m \exp(-\beta U_m)}{Z} \approx \frac{H_m}{N \Delta U}. \quad (3.1.4.8)$$

Therefore,

$$\begin{aligned} \Omega_m &= \frac{1}{\Delta U} \cdot \frac{H_m}{N} \cdot \frac{Z(\beta)}{\exp(-\beta U_m)} \\ &= \frac{H_m}{N \Delta U \exp[f - \beta U_m]}, \end{aligned} \quad (3.1.4.9)$$

and variances

$$\delta^2 \Omega_m = \frac{\delta^2 H_m}{(N \Delta U \exp[f - \beta U_m])^2}, \quad (3.1.4.10)$$

in which we have defined a dimensionless free energy  $f = -\ln Z(\beta)$ .

Practically, we may run multiple ( $K$ ) trajectories using, for example, replica exchange molecular dynamics simulations. For each trajectory (index  $k$ ), we have unique estimators for the histogram  $H_{mk}$ , the density of states  $\Omega_{mk}$  and their variances  $\delta^2 H_{mk}$  and  $\delta^2 \Omega_{mk}$  being

$$H_{mk} = \sum_{n=1}^{N_k} \psi_m(U(\mathbf{R}_{kn})), \quad (3.1.4.11)$$

$$\delta^2 H_{mk} = g_{mk} H_{mk} \left( 1 - \frac{H_{mk}}{N_k} \right), \quad (3.1.4.12)$$

$$\Omega_{mk} = \frac{H_{mk}}{N_k \Delta U \exp[f_k - \beta_k U_m]}, \quad (3.1.4.13)$$

and

$$\delta^2 \Omega_{mk} = \frac{\delta^2 H_{mk}}{(N_k \Delta U \exp[f_k - \beta_k U_m])^2}, \quad (3.1.4.14)$$

The optimum estimator of the density of states from all the simulations is

$$\Omega_m = \frac{\sum_{k=1}^K [\delta^2 \Omega_{mk}]^{-1} \Omega_{mk}}{\sum_{k=1}^K [\delta^2 \Omega_{mk}]^{-1}}, \quad (3.1.4.15)$$

which is the weighted average of density of states of all the trajectories with the weight reversely proportional to the variances (see Appendix B).

To make the expression simpler, here we take some approximations. First, normally the energy space is split into a large number of bins. The histogram in each bin is much smaller than the total number of snapshots, i.e.  $H_{mk} \ll N_k$ . The expectation of  $H_{mk}$  can be related to the optimum estimator of the density of states, i.e.

$$\overline{H_{mk}} = N_k \Delta U \Omega_m \exp(f_k - \beta_k U_m). \quad (3.1.4.16)$$

Then we have

$$\delta^2 H_{mk} = g_{mk} N_k \Delta U \Omega_m \exp(f_k - \beta_k U_m) \quad (3.1.4.17)$$

and

$$\delta^2 \Omega_{mk} = \frac{\Omega_m}{g_{mk}^{-1} N_k \Delta U \exp(f_k - \beta_k U_m)}. \quad (3.1.4.18)$$

Taking Eq. 3.1.4.13 and Eq. 3.1.4.18 into Eq. 3.1.4.15, we find

$$\Omega_m = \frac{\sum_{k=1}^K g_{mk}^{-1} H_{mk}}{\sum_{k=1}^K g_{mk}^{-1} N_k \Delta U \exp(f_k - \beta_k U_m)}, \quad (3.1.4.19)$$

in which

$$f_k = -\ln \sum_{m=1}^M \Omega_m \Delta U \exp(-\beta_k U_m). \quad (3.1.4.20)$$

Obviously, Eq. 3.1.4.19 and Eq. 3.1.4.20 must be solved iteratively. Applying the error propagation rule to Eq. 3.1.4.19 and using Eq. 3.1.4.17, the variance of  $\Omega_m$  is given by

$$\delta^2 \Omega_m = \frac{\Omega_m}{\sum_{k=1}^K g_{mk}^{-1} N_k \Delta U \exp(f_k - \beta_k U_m)}, \quad (3.1.4.21)$$

and the relative variance is given by

$$\frac{\delta^2 \Omega_m}{\Omega_m^2} = \left[ \sum_{k=1}^K g_{mk}^{-1} H_{mk} \right]^{-1}. \quad (3.1.4.22)$$

Using the density of states and its variance, we can estimate the expectation of any configuration function  $A(\mathbf{R})$  at any inverse temperature  $\beta$

$$\langle A \rangle_\beta \approx \frac{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m) A_m}{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m)}, \quad (3.1.4.23)$$

where

$$A_m = \frac{\int d\mathbf{R} A(\mathbf{R}) \psi_m(U(\mathbf{R}))}{\int d\mathbf{R} \psi_m(U(\mathbf{R}))}. \quad (3.1.4.24)$$

Using histograms of bin  $m$  from all the simulations and defining  $H_m = \sum_{k=1}^K H_{mk}$ , an estimator of  $A_m$  denoted as  $\hat{A}_m$  can be calculated as

$$\hat{A}_m = H_m^{-1} \sum_{k=1}^K \sum_{n=1}^{N_k} \psi_m(U(\mathbf{R}_{kn})) A(\mathbf{R}_{kn}). \quad (3.1.4.25)$$

Taking Eq. 3.1.4.25 into Eq. 3.1.4.23, we obtain an estimator of  $\hat{A}(\beta)$

$$\hat{A}(\beta) = \frac{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m) H_m^{-1} \sum_{k=1}^K \sum_{n=1}^{N_k} \psi_m(U(\mathbf{R}_{kn})) A(\mathbf{R}_{kn})}{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m)} \quad (3.1.4.26)$$

$$= \frac{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m) H_m^{-1} \sum_{k=1}^K \sum_{n=1}^{N_k} \psi_m(U(\mathbf{R}_{kn})) A(\mathbf{R}_{kn})}{\sum_{m=1}^M \Omega_m \Delta U \exp(-\beta U_m) H_m^{-1} \sum_{k=1}^K \sum_{n=1}^{N_k} \psi_m(U(\mathbf{R}_{kn}))} \quad (3.1.4.27)$$

$$= \frac{\sum_{k=1}^K \sum_{n=1}^{N_k} w_{kn}(\beta) A_{kn}}{\sum_{k=1}^K \sum_{n=1}^{N_k} w_{kn}(\beta)}, \quad (3.1.4.28)$$

where the per-configuration weights  $w_{kn}(\beta)$  is given by

$$w_{kn}(\beta) = \sum_{m=1}^M H_m^{-1} \psi_m(U(\mathbf{R}_{kn})) \Omega_m \exp(-\beta U_m) \quad (3.1.4.29)$$

### Weighted Histogram Analysis Method From Minimizing Statistical Error

In this section, the “traditional” derivation method of WHAM are briefly reviewed.[35] In the WHAM, the goal is to get an optimal unbiased probability distribution  $\rho_0(\eta)$ , where  $\eta$  is a series of discretized histogram bins indexed by  $j = 1, 2, 3, \dots, M$  along a certain reaction coordinate. WHAM can be used to analyze the Umbrella Sampling (US) simulations, where a set of simulations indexed by  $i$  or  $k = 1, 2, 3, \dots, S$  are performed with a series of biasing potentials added on the reaction coordinate  $\eta$ . To consider a reference molecular system with the potential energy  $U_0(\mathbf{x})$ , where  $\mathbf{x}$  is the set of atomic coordinates. The reaction coordinate  $\eta$  is a function of the atomic coordinates, i.e.  $\eta(\mathbf{x})$ . To suppose that the  $i$ th molecular simulation has been performed using potential energy function

$$U_i^{(b)}(\eta) = U_0(\mathbf{x}) + W_i(\eta(\mathbf{x})), \quad (3.1.4.30)$$

where  $W_i(\eta(\mathbf{x}))$  is the biasing potential added on the reaction coordinate  $\eta$ , e.g.  $W_i(\eta) = \frac{1}{2}k_i(\eta - \eta_i)^2$  in a Harmonic form. From these simulations a set of normalized biased probability distributions  $\rho_i^{(b)}(\eta)$  can be obtained.

$$\rho_i^{(b)}(\eta) = \frac{e^{-\beta U_i^{(b)}(\eta)}}{Q_i^{(b)}}, \quad (3.1.4.31)$$

where  $Q_i^{(b)} = \int e^{-\beta U_i^{(b)}(\eta)} d\eta = e^{-\beta f_i^{(b)}}$  and  $f_i^{(b)}$  is the biased free energy. The corresponding unnormalized unbiased probability distribution  $\rho_i^{(u)}(\eta)$  from the  $i$ th simulation is defined as,

$$\rho_i^{(u)}(\eta) = e^{\beta[W_i(\eta) - f_i^{(b)}]} \rho_i^{(b)}(\eta) \quad (3.1.4.32)$$

In the following, the free energy  $f_i^{(b)}$  is assumed to be known. It has been shown that in the WHAM method, the total normalized unbiased probability distribution  $\rho_0(\eta)$  can be obtained by a linear  $\eta$ -dependent combination of the unbiased histograms  $\rho_i^{(u)}(\eta)$

$$\rho_0(\eta) = C \sum_{i=1}^S p_i(\eta) \rho_i^{(u)}(\eta), \quad (3.1.4.33)$$

where  $C$  is the normalization factor.  $p_i$  is the weight to be optimized, which is under a constraint that

$$\sum_{i=1}^S p_i(\eta) = 1. \quad (3.1.4.34)$$

These weights are chosen so as to minimize the statistical error made on the total unbiased probability distribution  $\rho_0(\eta)$ , that is, for any given value of

$\eta$ ,

$$\frac{\partial(\sigma^2[\rho_0(\eta)])}{\partial p_i(\eta)} = 0. \quad (3.1.4.35)$$

It can be easily found that  $\rho_0(\eta)$  satisfy

$$\begin{aligned} \rho_0(\eta) &= C \sum_{i=1}^S \frac{N_i e^{-\beta[W_i(\eta) - f_i^{(b)}]}}{\sum_{k=1}^S N_k e^{-\beta[W_k(\eta) - f_k^{(b)}]}} \rho_i^{(u)}(\eta) \\ &= C \sum_{i=1}^S \frac{N_i}{\sum_{k=1}^S N_k e^{-\beta[W_k(\eta) - f_k^{(b)}]}} \rho_i^{(b)}(\eta) \\ &= C \frac{\sum_{i=1}^S N_i \rho_i^{(b)}(\eta)}{\sum_{k=1}^S N_k e^{-\beta[W_k(\eta) - f_k^{(b)}]}}, \end{aligned} \quad (3.1.4.36)$$

where  $\rho_i^{(b)}(\eta)$  can be written as a  $\delta$  function,

$$\rho_i^{(b)}(\eta) \equiv \frac{1}{N_i} \sum_{l=1}^{N_i} \delta(\eta - \eta_{i,l}), \quad (3.1.4.37)$$

where  $\eta_{i,l}$  is the reaction coordinates of the  $l$ th configuration in the  $i$ th biased simulation .

Until now, the treatment assumes that the free energy parameters  $f_i^{(b)}$  are known. In fact, these parameters can be obtained self-consistently. Indeed, the definition of the free energy  $f_i^{(b)}$  is,

$$\begin{aligned} e^{-\beta f_i^{(b)}} &= \int e^{-\beta U_i^{(b)}(\eta)} d\eta \\ &= \int \rho_0(\eta) e^{-\beta W_i(\eta)} d\eta \\ &= C \int \frac{\sum_{i=1}^S N_i \rho_i^{(b)}(\eta)}{\sum_{k=1}^S N_k e^{-\beta[W_k(\eta) - f_k^{(b)}]}} e^{-\beta W_i(\eta)} d\eta \end{aligned} \quad (3.1.4.38)$$

The set of parameters  $f_i^{(b)}$  appear on both sides of Eq. 3.1.4.38, which must be solved iteratively. A initial guess of the values  $f_i^{(b)0}$  is used on the right side of Eq. 3.1.4.38 to compute a new set of values  $f_i^{(b)1}$ , which is in turn used as the new guess to compute  $f_i^{(b)1}$  and so on until convergence is reached. Then, the unbiased free energy corresponding to the histogram can be calculated by,

$$f_0(\eta) = -\beta^{-1} \ln \rho_0(\eta) \quad (3.1.4.39)$$

To get rid of the constant  $C$  in the Eq. 3.1.4.36, one may subtract the offset constant  $f_0(\eta_1)$  from all the  $f_0(\eta_j)$ .

### Weighted Histogram Analysis Method From Maximum Likelihood

The following derivation quite follows Ref. [36], in which maximum likelihood principle is utilized. Suppose we have performed  $K$  simulations, each at a different inverse temperature  $\beta_k$  and possibly with different biasing potential  $w_k(\mathbf{R})$ . We then discretize the 2D plane spanned by the coordinate and unbiased potential energy into bins, each characterized by  $\mathbf{R}_j$  and  $E_h$ . To make the following derivation cleaner, we map the 2D bins to one dimensional series with index  $l, l = 1, \dots, L$ . Next, we construct histograms for bins using all the samples from the simulations. The probability of finding the system in bin  $l$  during the  $k$ th simulation can be written as

$$p_{k,l} = f_k c_{k,l} p_l^0, \quad (3.1.4.40)$$

in which  $p_l^0$  is the (simulation-independent) unbiased probability,

$$\begin{aligned} c_{k,l} &= \exp[-\beta_k(E_l + w_{k,l}) + \beta_0 E_l] \\ &= \exp[-(\beta_k - \beta_0) E_l] \exp(-\beta_k w_{k,l}) \end{aligned} \quad (3.1.4.41)$$

is the bias factor,  $E_l$  is the unbiased energy of bin  $l$ ,  $f_k = \left\{ \sum_l c_{k,l} p_l^0 \right\}^{-1}$  is the normalization factor. It is worth emphasizing that the biasing potential can be multiple dimensional as, for instance, in a two-dimensional umbrella sampling. If the biasing is only in temperature-space as in replica exchange molecular dynamics

$$c_{k,l} = \exp[-(\beta_k - \beta_0) E_l], \quad (3.1.4.42)$$

while if the biasing is only in potential energy as in umbrella sampling

$$c_{k,l} = \exp(-\beta_0 w_{k,l}). \quad (3.1.4.43)$$

If we assume that each count in each histogram is independent, then the likelihood of observing the  $k$ th histogram distribution is given by the multinomial distribution

$$\begin{aligned} P(n_{k,1}, n_{k,2}, \dots, n_{k,L} | p_{k,1}, p_{k,2}, \dots, p_{k,L}) = \\ \frac{\left( \sum_l n_{k,l} \right)!}{\prod_l n_{k,l}!} \prod_{l=1}^L (p_{k,l})^{n_{k,l}} \propto \prod_{l=1}^L \left( f_k c_{k,l} p_l^0 \right)^{n_{k,l}}. \end{aligned} \quad (3.1.4.44)$$

For all  $K$  simulations, the likelihood is the product of multinomial

$$\begin{aligned} P(n_{1,1}, \dots, n_{1,L}; \dots; n_{K,1}, \dots, n_{K,L} | p_1^0, \dots, p_L^0) \propto \\ \prod_{k=1}^K \prod_{l=1}^L \left( f_k c_{k,l} p_l^0 \right)^{n_{k,l}}, \end{aligned} \quad (3.1.4.45)$$

where the likelihood is conditional only on the unbiased probabilities  $p_l^0$ , since the bias factors  $c_{k,l}$  are known parameters, and the normalization constants  $f_k$  are known conditional on  $p_l^0$ . The maximum likelihood estimate of the unbiased probabilities can be found by maximizing  $P$  in Eq. 3.1.4.45 with respect to  $p_1^0, \dots, p_L^0$  and are given by solutions of the simultaneous nonlinear equations

$$p_l^0 = \frac{\sum_{k=1}^K n_{k,l}}{\sum_{k=1}^K N_k f_k c_{k,l}} \quad (\text{for each } l) \quad (3.1.4.46)$$

and

$$f_k = \left\{ \sum_l c_{k,l} p_l^0 \right\}^{-1}, \quad (3.1.4.47)$$

where  $N_k$  is the total number of counts in the  $k$ th histogram.

### Binless Weighted Histogram Analysis Method

The following derivation quite follows Ref. [37]. Let us start with the definition of a generalized energy function  $u$  and its corresponding coefficient  $\theta$ . For instance, for canonical ensemble,  $u = U(x)$  is the potential energy function, and  $\theta = \beta$  is the inverse temperature. For isothermal grand-canonical ensemble,  $u = (U(x), N)$ , and  $\theta = (\beta, \beta\mu)$ , in which  $N$  is the number of particles and  $\mu$  is the chemical potential. For temperature replica exchange molecular dynamics,  $u = U(x)$  and  $\theta_k = \beta_k$  for the  $k$ th replica. For umbrella sampling,  $u = (U_0(x), \omega_1(x), \omega_2(x), \dots, \omega_d(x))$ , where  $U_0(x)$  is the unbiased Hamiltonian and  $\omega_k(x)$  is the biasing potential in window  $k$ . Correspondingly,  $\theta_k = (\beta, 0, \dots, 0, \beta, 0, \dots, 0)$ , in which all the elements are zero except for the first and the  $(k+1)$ th element.

Assume that simulations are conducted at  $m$  coefficient vectors  $\theta_r$  ( $r = 1, \dots, m$ ) and with the same energy vector  $u(x)$ . (Note that in this notation the dimensionality,  $d$ , of the  $\theta$  and  $u$  vectors and the number of simulations,  $m$ , are, in general, distinct. For instance, for temperature replica exchange molecular dynamics as shown above,  $d = 1$ , while  $m$  is the number of replicas.) Denoted by  $\{x_{ji} : i = 1, \dots, n_j\}$  the set of configurations of size  $n_j$  from the the  $j$ th simulation, and denoted by  $u_{ji} = u(x_{ji})$  the corresponding generalized energy vectors. The total sample size is  $n = \sum_{j=1}^m n_j$ . Now, consider a generalized ensemble whose Boltzmann probability density function is

$$\frac{1}{Z_\theta} e^{-\theta^T u(x)}, \quad (3.1.4.48)$$

where

$$Z_\theta = \int e^{-\theta^T u(x)} dx \quad (3.1.4.49)$$

is the generalized configurational integral in physics or the normalization constant in statistics, and the superscript T is the transpose operator. The induced probability density function of  $u(x)$  at  $\theta$  is

$$\frac{1}{Z_\theta} \Omega(u) e^{-\theta^T u}, \quad (3.1.4.50)$$

where  $\Omega(u)$ , formally defined as

$$\Omega(u) = \int \delta(u(x) - u) dx, \quad (3.1.4.51)$$

is a generalized density of states, which does not depend on  $\theta$ . The generalized configurational integral can also be determined from  $\Omega(u)$  as

$$Z_\theta = \int \Omega(u) e^{-\theta^T u} du. \quad (3.1.4.52)$$

As we have shown that the WHAM method involves constructing a histogram,  $H_r(u)$ , from each sample  $\{u_{ri} : i = 1, \dots, n_r\}$ , which  $H_r(u)$  indicates the number of observations falling into a bin about  $u$ , for example, an interval or a rectangle if  $u(x)$  is one or two-dimensional. Then  $\Omega(u)$  is estimated by

$$\hat{\Omega}(u) \Delta u = \frac{\sum_{r=1}^m H_r(u)}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{-\theta_r^T u}}, \quad (3.1.4.53)$$

where the configurational integrals  $(Z_{\theta_1}, \dots, Z_{\theta_m})$  are defined by self-consistency according to Eq. 3.1.4.53

$$\hat{Z}_{\theta_k} = \sum_u \frac{\sum_{r=1}^m H_r(u)}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta_k - \theta_r)^T u}} \quad (k = 1, \dots, m), \quad (3.1.4.54)$$

where the summation  $\sum_u$  is taken over all possible bins centered at  $u$  of size  $\Delta u$ . Also, the configurational integral  $Z_\theta$  at any other parameter value is estimated by

$$\hat{Z}_\theta = \sum_u \frac{\sum_{r=1}^m H_r(u)}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^T u}}. \quad (3.1.4.55)$$

We can take

$$\frac{1}{\hat{Z}_\theta} \frac{\sum_{r=1}^m H_r(u)}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^T u}} \quad (3.1.4.56)$$

as the weight of bin  $u$ .

Now, let  $h(u)$  be a function of  $u$ , and denoted by  $\langle h \rangle_\theta$  the expectation of  $h(u)$ . The WHAM estimate  $\hat{h}_\theta$  for  $\langle h \rangle_\theta$  is

$$\hat{h}_\theta = \frac{1}{\hat{Z}_\theta} \sum_u h(u) \frac{\sum_{r=1}^m H_r(u)}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^T u}}. \quad (3.1.4.57)$$

It is interesting to note that the summation over bins in Eq. 3.1.4.57 can be equivalently expressed in terms of a weighted average over observations

$$\hat{h}_\theta = \sum_{ji} h(u_{ji}^b) F_{ji}(\theta), \quad (3.1.4.58)$$

where  $u_{ji}^b$  is a representative generalized energy of the bin containing  $u_{ji}$ ,  $F_{ji}$  is the “WHAM weight” of  $u_{ji}$  that, by comparing Eqs. 3.1.4.57 and 3.1.4.58, is defined as

$$F_{ji}(\theta) = \frac{\hat{Z}_\theta^{-1}}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^T u_{ji}^b}} = \frac{1}{\hat{Z}_\theta} e^{-\theta^T u_{ji}^b} G_{ji} \quad (3.1.4.59)$$

and

$$G_{ji} = \frac{1}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{-\theta_r^T u_{ji}^b}} \quad (3.1.4.60)$$

is the  $\theta$ -dependent component of the WHAM weight  $F_{ji}(\theta)$  for each observation.

Equation 3.1.4.58 states that the expectation value of any observable can be obtained by attaching a statistical weight  $F_{ji}(\theta)$  to each observation  $u_{ji}$  which depends on the bin to which it is assigned. An obvious simplification is to express the WHAM estimate of  $\langle h \rangle_\theta$  and the WHAM weights (Eq. 3.1.4.59) in terms of the actual observation  $u_{ji}$  rather than their closest bin representative  $u_{ji}^b$ .

To understand binless WHAM, it is useful to introduce the concept of the measure  $G$  defined by

$$dG = \Omega(u) du, \quad (3.1.4.61)$$

that is,  $G(A) = \int_A \Omega(u) du$  for every measurable set  $A$  of  $u$ . Informally, this equation says that for an infinitesimal bin about  $u$  of size  $du$ , the weight assigned under  $G$  is  $\Omega(u) du$ . Thereafter  $G$  is called the measure of states. The probability distribution of  $u(x)$ ,  $F_\theta$ , is related to  $G$  as

$$dF_\theta = \frac{1}{Z_\theta} e^{-\theta^T u} \Omega(u) du = \frac{1}{Z_\theta} e^{-\theta^T u} dG, \quad (3.1.4.62)$$

that is

$$F_\theta(A) = \frac{1}{Z_\theta} \int_A e^{-\theta^T u} dG \quad (3.1.4.63)$$

for every measurable set  $A$  of  $u$ . The configurational integral can then be expressed as

$$Z_\theta = \int e^{-\theta^T u} dG. \quad (3.1.4.64)$$

The pooled data  $\{u_{ji} : i = 1, \dots, n_j, j = 1, \dots, m\}$  can be regarded as an approximate sample from the mixture distribution,  $F_*$ , whose components are  $(F_{\theta_1}, \dots, F_{\theta_m})$  with proportions  $(n_1/n, \dots, n_m/n)$ .  $F_*$  is related to  $G$  as

$$dF_* = \left\{ \sum_{r=1}^m \frac{n_r}{n} Z_{\theta_r}^{-1} e^{-\theta_r^T u} \right\} \Omega(u) du = \left\{ \sum_{r=1}^m \frac{n_r}{n} Z_{\theta_r}^{-1} e^{-\theta_r^T u} \right\} dG \quad (3.1.4.65)$$

For an infinitesimal bin about  $u$  of size  $du$ , the probability assigned under  $F_*$  is the expression in the curly brackets times the weight assigned under  $G$ . Dividing both sides of Eq. 3.1.4.65 by the quantity in the curly brackets gives

$$dG = \left\{ \sum_{r=1}^m \frac{n_r}{n} Z_{\theta_r}^{-1} e^{-\theta_r^T u} \right\}^{-1} dF_*. \quad (3.1.4.66)$$

For an infinitesimal bin about  $u$  of size  $du$ , the weight assigned under  $G$  is the inverse of the quantity in the curly brackets times the probability assigned under  $F_*$ .

Relationship (3.1.4.66) can be used for estimating  $G$  from the pooled data by importance weighting. Recall that the pooled data form an approximate sample from  $F_*$ . Then  $F_*$  can be estimated by the empirical distribution  $\hat{F}_*$  for which each observation  $u_{ji}$  is assigned the probability  $n^{-1}$ . By Eq. 3.1.4.66, the resulting estimator  $\hat{G}$  is a discrete measure for which each observation  $u_{ji}$  is assigned the weight

$$\hat{G}(u_{ji}) = \frac{1}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{-\theta_r^T u_{ji}}}, \quad (3.1.4.67)$$

where

$$\begin{aligned} \hat{Z}_{\theta_k} &= \sum_{j=1}^m \sum_{i=1}^{n_j} e^{-\theta_k^T u_{ji}} \hat{G}(u_{ji}) \\ &= \sum_{j=1}^m \sum_{i=1}^{n_j} \frac{1}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta_k - \theta_r)^T u_{ji}}} \quad (k = 1, \dots, m). \end{aligned} \quad (3.1.4.68)$$

Formulas 3.1.4.67 and 3.1.4.68 provide a binless extension of Eq. 3.1.4.53 and 3.1.4.54 in WHAM.

Again, the configurational integral  $Z_\theta$  at any other parameter value is estimated by

$$\begin{aligned} \hat{Z}_\theta &= \sum_{j=1}^m \sum_{i=1}^{n_j} e^{-\theta^T u_{ji}} \hat{G}(u_{ji}) \\ &= \sum_{j=1}^m \sum_{i=1}^{n_j} \frac{1}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^T u_{ji}}}. \end{aligned} \quad (3.1.4.69)$$

The expectation  $\langle h \rangle_\theta$  is by definition  $Z_\theta^{-1} \int h(u) e^{-\theta^\top u} dG$  and hence estimated by

$$\begin{aligned} & \frac{1}{\hat{Z}_\theta} \sum_{j=1}^m \sum_{i=1}^{n_j} h(u_{ji}) e^{-\theta^\top u_{ji}} \hat{G}(u_{ji}) \\ &= \frac{1}{\hat{Z}_\theta} \sum_{j=1}^m \sum_{i=1}^{n_j} \frac{h(u_{ji})}{\sum_{r=1}^m n_r \hat{Z}_{\theta_r}^{-1} e^{(\theta - \theta_r)^\top u_{ji}}}. \end{aligned} \quad (3.1.4.70)$$

Formulas 3.1.4.69 and 3.1.4.70 provide a binless extension of Eqs. 3.1.4.55 and 3.1.4.57 in WHAM.

### 3.1.5 Multistate Bennett Acceptance Ratio

*“An alleged scientific discovery has no merit unless it can be explained to a barmaid.”*

– Ernest Rutherford

*“So, you can never be a good scientist unless you go to bar regularly.”*

– Yihan Shao

The Multistate Bennett Acceptance Ratio (MBAR) method was developed by Shirts and Chodera in 2008.[38] The following derivation quite follows Ref. [39] Imaging you have carried out a series of simulations such as umbrella sampling, or replica exchange molecular dynamics simulations. Now you have  $K$  trajectories in total and each trajectory is characterized by Hamiltonian  $H_k$  and inverse temperature  $\beta_k$ . The trajectories unnecessarily have the same number of conformations. Instead, the number of conformations in trajectory  $k$  is  $N_k$ . Now, you mix all the samples and randomly pick one sample out of them. The probability for this sample to have coordinates  $\mathbf{R}$  is

$$p_m(\mathbf{R}) = \frac{1}{N} \sum_{k=1}^K N_k p_k(\mathbf{R}), \quad (3.1.5.1)$$

in which  $N = \sum_{k=1}^K N_k$  and the subscript  $m$  means mixed ensemble.  $p_k(\mathbf{R}_n)$  is the probability of finding this snapshot in trajectory  $k$ , which satisfies

$$p_k(\mathbf{R}) = c_k^{-1} q_k(\mathbf{R}). \quad (3.1.5.2)$$

$c_k$  is the normalization constant. You can see that this mixed ensemble does not follow Boltzmann statistics, even if  $q_k$  does. It can be proved that if  $p_k$  is normalized, then  $p_m$  is also normalized.

The expectation of any operator  $\hat{O}$  averaged over this mixed ensemble can be calculated by

$$\langle O \rangle_m = \int O(\mathbf{R}) p_m(\mathbf{R}) d\mathbf{R} \approx \frac{1}{N} \sum_{n=1}^N O(\mathbf{R}_n). \quad (3.1.5.3)$$

Using energy reweighting[9], we can calculate the expectation of this operator under any other Hamiltonian  $H_i$  and probability  $p_i$ , which can be

expressed as

$$\begin{aligned}
\langle O \rangle_i &= \int O(\mathbf{R}) p_i(\mathbf{R}) d\mathbf{R} \\
&= \int O(\mathbf{R}) \frac{p_i(\mathbf{R})}{p_m(\mathbf{R})} p_m(\mathbf{R}) d\mathbf{R} \\
&\approx \frac{1}{N} \sum_{n=1}^N O(\mathbf{R}_n) \frac{p_i(\mathbf{R}_n)}{p_m(\mathbf{R}_n)} \\
&= \frac{1}{N} \sum_{n=1}^N O(\mathbf{R}_n) c_i^{-1} \frac{q_i(\mathbf{R}_n)}{p_m(\mathbf{R}_n)} \\
&= \sum_{n=1}^N O(\mathbf{R}_n) c_i^{-1} \frac{q_i(\mathbf{R}_n)}{\sum_{k=1}^K N_k p_k(\mathbf{R}_n)} \tag{3.1.5.4}
\end{aligned}$$

Let  $O = 1$ , we find

$$1 = \sum_{n=1}^N c_i^{-1} \frac{q_i(\mathbf{R}_n)}{\sum_{k=1}^K N_k p_k(\mathbf{R}_n)}. \tag{3.1.5.5}$$

Since  $c_i$  does not depend on  $n$ ,

$$\begin{aligned}
c_i &= \sum_{n=1}^N \frac{q_i(\mathbf{R}_n)}{\sum_{k=1}^K N_k p_k(\mathbf{R}_n)} \\
&= \sum_{n=1}^N \frac{q_i(\mathbf{R}_n)}{\sum_{k=1}^K N_k c_k^{-1} q_k(\mathbf{R}_n)} \tag{3.1.5.6}
\end{aligned}$$

In Boltzmann statistics,  $q_k(\mathbf{R}) = \exp[-\beta_k U_k(\mathbf{R})]$  and  $c_k = \int q_k(\mathbf{R}) d\mathbf{R}$  is the partition function or the normalization constant. *Note that we have not assumed anything about the statistics of ensemble  $k$  and  $i$ . Besides,  $i$  is unnecessarily within  $\{k\}$ . For instance, if we run replica exchange molecular dynamics simulations at  $K$  inverse temperatures  $\beta_1, \dots, \beta_K$ ,  $\beta_i$  can be either one of these inverse temperatures or any other inverse temperature between  $\beta_1$  and  $\beta_K$ . But extrapolation to inverse temperatures outside the range of  $[\beta_K, \beta_1]$  is not recommended.*

If  $q_k$  and  $q_i$  follow Boltzmann statistics, and we define free energy  $f_i = -\beta_i^{-1} \ln c_i$ , Eq. 3.1.5.6 becomes

$$f_i = -\beta_i^{-1} \ln \sum_{n=1}^N \frac{\exp(-\beta_i U_i(\mathbf{R}_n))}{\sum_{k=1}^K N_k \exp(\beta_k f_k - \beta_k U_k(\mathbf{R}_n))}, \tag{3.1.5.7}$$

which must be solved self-consistently and can be determined up to a constant. We can fix  $f_1$  (to 0 usually).

Again, from Eq. 3.1.5.4, we can define

$$W_{in} = c_i^{-1} \frac{q_i(\mathbf{R}_n)}{\sum_{k=1}^K N_k c_k^{-1} q_k(\mathbf{R}_n)}, \tag{3.1.5.8}$$

which is the weight of snapshot  $n$  in ensemble  $i$  determined by Hamiltonian  $H_i$  and temperature  $\beta_i$ . Specifically, for the Boltzmann statistics,

$$W_{in} = \frac{e^{-\beta_i[U_i(\mathbf{R}_n) - f_i]}}{\sum_{k=1}^K N_k e^{-\beta_k[U_k(\mathbf{R}_n) - f_k]}}. \quad (3.1.5.9)$$

### 3.1.6 Non-Equilibrium Work

#### Non-Equilibrium Work for Free Energy Difference between Two States

Non-Equilibrium Work (NEW) method for equilibrium free energy calculations was proposed by Jarzynski.[40]. In 1997, Jarzynski showed

$$\langle \exp[-\beta W(\tau)] \rangle = \exp(-\beta \Delta A), \quad (3.1.6.1)$$

which is now called the Jarzynski equality. Here,  $W$  is the accumulated work along a path  $\lambda(t)$  connecting the initial and final states, with  $\lambda(0) = 0$  and  $\lambda(\tau) = 1$ , and  $\Delta A = A(1) - A(0)$  the free energy difference between these two states.  $\langle \cdots \rangle$  in Eq. 3.1.6.1 is an average over a series of trajectories with the initial conditions chosen according to the equilibrium Boltzmann probability in state  $\lambda(0)$ . The path average samples all the realizations of dynamic paths weighted by their respective path actions under the time evolution of the system with an explicitly time-dependent Hamiltonian. This equality was also obtained by Crooks for markovian and microscopically reversible dynamics.[41]

Now, we consider creating an equilibrium configuration for the state  $\lambda = 0$  and then slowly changing  $\lambda$  from 0 to 1. As the coupling parameter advances, the system continues to sample phase space by molecular dynamics or Monte Carlo simulations, but under an explicitly time-dependent Hamiltonian. In the limit of a very slow transformation, the system will remain close to the equilibrium. The free energy difference can then be evaluated by changing  $\lambda$  continuously

$$\Delta A = \lim_{\tau \rightarrow \infty} \int_0^\tau \left. \frac{\partial H[\mathbf{x}(t); \lambda]}{\partial \lambda} \right|_{\lambda=\lambda(t)} \dot{\lambda}(t) dt, \quad (3.1.6.2)$$

where  $\dot{\lambda}(t)$  is the time derivative of the coupling parameter  $\lambda$ . In Eq. 3.1.6.2, the limit of  $\tau \rightarrow \infty$  ensures that the transformation is performed infinitely slowly, and thus reversibly. The right-hand side of Eq. 3.1.6.2 is the “reversible work” done to the system during the transformation.

If the system is instead transformed between the initial and final states over a finite time interval  $\tau$ , the system will not be able to sample the phase space exhaustively at each value of  $\lambda$ , making this transformation irreversible. As the transformation proceeds, the system will be gradually driven out of equilibrium, causing hysteresis effects. From the second law of thermodynamic, it is expected that the work  $W(\tau)$  performed during the nonequilibrium transformation is on average larger than or equal to the free energy difference between the two states

$$\langle W(\tau) \rangle \geq \Delta A, \quad (3.1.6.3)$$

and the difference accounts for heat-dissipation effect. The work  $W(\tau)$  performed on the system is the accumulated energy cost required to change the system

$$W(\tau) = \int_0^\tau \left. \frac{\partial H[\mathbf{x}(t); \lambda]}{\partial \lambda} \right|_{\lambda=\lambda(t)} \dot{\lambda}(t) dt \quad (3.1.6.4)$$

The equality in Eq. 3.1.6.3 will normally be achieved only if the transformation is infinitely slow,  $\tau \rightarrow \infty$ . For paths of finite length, the amount of dissipated work,  $\langle W(\tau) \rangle - \Delta A \geq 0$ , depends on the chosen transformation path  $\lambda(t)$ .

Jarzynski equality, Eq. 3.1.6.1, immediately leads to the second law in the form of Eq. 3.1.6.3 because of the Jensen's inequality,  $\langle e^{-x} \rangle \geq e^{-\langle x \rangle}$ . Moreover, TI and TP can be thought as the limiting cases of the nonequilibrium process. When  $\tau \rightarrow \infty$  or  $\dot{\lambda}(t) \rightarrow 0$ , this is an infinitely slow transformation and the Eq. 3.1.6.2 is the formula of TI

$$\Delta A = \int_{\lambda=0}^{\lambda=1} \left\langle \frac{\partial H(\mathbf{x}, \mathbf{p}_x, \lambda)}{\partial \lambda} \right\rangle_\lambda d\lambda \quad (3.1.6.5)$$

When  $\tau \rightarrow 0$  or  $\dot{\lambda}(t) \rightarrow \infty$ , this is an infinitely fast transformation where the configurations will not relax and the work is simply the change in the Hamiltonian when going from the initial to the final state,

$$\lim_{\tau \rightarrow 0} W(\tau) = H(\mathbf{x}(0); \lambda = 1) - H(\mathbf{x}(0); \lambda = 0) \quad (3.1.6.6)$$

Substituting the Eq. 3.1.6.6 into the Eq. 3.1.6.1, the formula of TP can be recovered

$$\Delta A = -\frac{1}{\beta} \ln \langle \exp[-\beta \Delta H(\mathbf{x}, \mathbf{p}_x)] \rangle_0, \quad (3.1.6.7)$$

In Ref. [41], Crooks showed that the distributions of work values from the forward and the backward paths satisfy a relation that is central to the histogram methods in free energy calculations

$$\frac{p_f[w = W(\tau)]}{p_b[w = -\underline{W}(\tau)]} = \exp[\beta(w - \Delta A)], \quad (3.1.6.8)$$

where  $p_f[w = W(\tau)]$  and  $p_b[w = -\underline{W}(\tau)]$  are the probability densities of the work values in the forward and the reverse transformations (with a sign change for the work in the reverse path). Both are normalized, i.e.,  $\int p_f(w) dw = \int p_b(w) dw = 1$ . It is noted that Jarzynski equality Eq. 3.1.6.1 follows from Eq. 3.1.6.8 simply by integration over  $w$  because the probability densities are normalized to 1:

$$\int p_f(W) e^{-\beta W} dW = \int p_b(W) e^{-\beta \Delta A} dW, \quad (3.1.6.9)$$

Because of the normalization condition, the right-hand side is equal to  $\exp(-\beta \Delta A)$ , and Jarzynski equality follows.

Figure 3.3: The accumulation of work and heat along a nonequilibrium trajectory. The work is defined as the energy change when the coupling parameter switches from  $\lambda_i$  to  $\lambda_{i+1}$  with the coordinates fixed, while the dissipated heat is defined as the energy relaxation when the coordinate change with the coupling parameter fixed.

Following the Crooks Fluctuation Theorem (CFT),[41] Bennett acceptance ratio can be applicable to nonequilibrium calculations. This approach was combined with a maximum likelihood estimate, and accurate free energy differences were obtained.[31] In this approach,  $\Delta A$  is calculated via

$$\sum_{i=1}^{n_F} \frac{1}{1 + \exp [\beta(M + W_i - \Delta A)]} = \sum_{j=1}^{n_R} \frac{1}{1 + \exp [-\beta(M + W_j - \Delta A)]}, \quad (3.1.6.10)$$

where  $n_F$  and  $n_R$  are the numbers of the forward and reverse transformations respectively,  $W_i$  and  $W_j$  are the work of forward and reverse measurements respectively, and  $M = \beta^{-1} \ln(n_F/n_R)$ . The corresponding statistical variance of  $\Delta A$ ,  $\sigma^2$ , is calculated using Eq. 10 in Ref. [31].

### Non-Equilibrium Work for Free Energy Profiles

When calculating the free energy profile in a pulling experiment, the Jarzynski equality is no longer straightforwardly applicable, because it relates the nonequilibrium work to free energy differences at different times, not positions along a predefined reaction coordinate. In order to surmount this difficulty, Hummer and Szabo extended the Jarzynski equality by measuring force/extension along pulling.[42]

Let us begin with a system of which the phase-space density evolves according to a Liouville-type equation:

$$\frac{\partial f(\mathbf{x}, t)}{\partial t} = \mathcal{L}_t f(\mathbf{x}, t). \quad (3.1.6.11)$$

$\mathcal{L}_t$  is an explicitly time-dependent evolution operator that has the Boltzmann distribution as a stationary solution,  $\mathcal{L}_t e^{-\beta \mathcal{H}(\mathbf{x}, t)} = 0$ , where  $\mathcal{H}(\mathbf{x}, t)$  is a time-dependent Hamiltonian. For diffusive dynamics on a potential  $V(\mathbf{x}, t)$ , the time evolution is governed by  $\mathcal{L}_t = D \nabla e^{-\beta V(\mathbf{x}, t)} \nabla e^{\beta V(\mathbf{x}, t)}$ , where  $D$  is the diffusion coefficient and  $\nabla = \partial/\partial \mathbf{x}$ . Now consider the unnormalized Boltzmann distribution at time  $t$ ,

$$p(\mathbf{x}, t) = \frac{e^{-\beta \mathcal{H}(\mathbf{x}, t)}}{\int e^{-\beta \mathcal{H}(\mathbf{x}', 0)} d\mathbf{x}'}. \quad (3.1.6.12)$$

Because this distribution is stationary ( $\mathcal{L}_t p = 0$ ), and because  $\partial p/\partial t = -\beta(\partial \mathcal{H}/\partial t)p$ , it follows that the above  $p(\mathbf{x}, t)$  is a solution of the sink equation

$$\frac{\partial p}{\partial t} = \mathcal{L}_t p - \beta \frac{\partial \mathcal{H}}{\partial t} p, \quad (3.1.6.13)$$

of which the solution, starting from an equilibrium distribution at time  $t = 0$ , can be expressed as a path integral by using the Feynman-Kac theorem. Equating these two differential solutions immediately gives:

$$\frac{e^{-\beta \mathcal{H}(\mathbf{x}, t)}}{\int e^{-\beta \mathcal{H}(\mathbf{x}', 0)} d\mathbf{x}'} = \left\langle \delta(\mathbf{x} - \mathbf{x}_t) \exp \left[ -\beta \int_0^t \frac{\partial \mathcal{H}}{\partial t'}(\mathbf{x}_{t'}, t') dt' \right] \right\rangle. \quad (3.1.6.14)$$

The average  $\langle \dots \rangle$  is over an ensemble of trajectories starting from the equilibrium distribution at  $t = 0$  and evolving according to Eq. 3.1.6.11. Each trajectory is weighted with the Boltzmann factor of the external work  $w_t$  done to the system,

$$w_t = \int_0^t \frac{\partial \mathcal{H}}{\partial t'}(\mathbf{x}_{t'}, t') dt'. \quad (3.1.6.15)$$

Integrating on both sides of Eq. 3.1.6.14 with respect to  $\mathbf{x}$ , we obtain Jarzynski equality

$$e^{-\beta \Delta G(t)} \equiv \frac{\int e^{-\beta \mathcal{H}(\mathbf{x}, t)} d\mathbf{x}}{\int e^{-\beta \mathcal{H}(\mathbf{x}, 0)} d\mathbf{x}} = \left\langle e^{-\beta w_t} \right\rangle \quad (3.1.6.16)$$

between the Boltzmann-averaged work  $w_t$  and the equilibrium free energy difference  $\Delta G(t)$  between times  $t$  and 0.

In a single-molecule pulling experiment, e.g. using atomic force microscope (AFM), the sample is moved at a constant speed  $v$  relative to the cantilever with spring constant  $k$ . The position  $z_t = vt + \delta z_t$  of the cantilever tip with respect to the sample is recorded, where  $\delta z_t$  is the displacement of the cantilever tip. It can be described by a Hamiltonian  $\mathcal{H}(\mathbf{x}, t) = \mathcal{H}_0(\mathbf{x}) + k(z - vt)^2/2$ , where  $\mathcal{H}_0(\mathbf{x})$  is the Hamiltonian of the resting, unperturbed system, and  $z = z(\mathbf{x})$ . Substituting this Hamiltonian into Eq. 3.1.6.14, multiplying both sides by  $\delta[z - z(\mathbf{x})]$ , integrating over all

$\mathbf{x}$ , and finally taking the logarithm, we have:

$$\begin{aligned} G_0(z) &\equiv -\beta^{-1} \ln \frac{\int \delta[z - z(\mathbf{x})] e^{-\beta \mathcal{H}_0(\mathbf{x})} d\mathbf{x}}{\int e^{-\beta \mathcal{H}(\mathbf{x}, 0)} d\mathbf{x}} \\ &= -\beta^{-1} \ln \langle \delta(z - z_t) e^{-\beta \Delta w_t} \rangle, \end{aligned} \quad (3.1.6.17)$$

where  $G_0(z)$  is the unperturbed free energy profile along the pulling coordinate  $z$ , and  $\Delta w_t$  is the external work minus the instantaneous biasing potential,  $\Delta w_t = w_t - k(z_t - vt)^2/2 = kv(vt^2/2 - \int_0^t z_{t'} dt') - k(z_t - vt)^2/2$ . The expression can be obtained by integrating the power over time. At any moment  $t'$ , the force acting on the system is  $f = k(vt' - z_{t'})$ . Correspondingly, the power  $p = f \cdot v$ . Therefore,  $w_t = \int p dt' = \int_0^t kv(vt' - z_{t'}) dt' = kv(vt^2/2 - \int_0^t z_{t'} dt')$ . At time  $t = 0$ , the trajectories are started from points  $z_0$  drawn from a Boltzmann distribution corresponding to Hamiltonian  $\mathcal{H}(\mathbf{x}, 0) = \mathcal{H}_0(\mathbf{x}) + kz^2/2$ , which is *NOT*  $\mathcal{H}_0(\mathbf{x})$ .

At each time slice  $t$ , one can in principle obtain an estimate of the whole free energy surface. In practice with finite number of trajectories, at any give time  $t$ , only a narrow region around the equilibrium position  $z = vt$  will be sampled adequately. Thus, an average over several time slices and repeated trajectories is required to obtain an optimal estimate of the free energy profile. At every time slice  $t$ , one obtains an ensemble of positions  $z_t$  and corresponding  $w_t$ s. The position  $z_t$  are binned, and the corresponding histogram values are incremented by  $e^{-\beta w_t}$ . The complete free energy profile  $G_0(z)$  can be reconstructed by adapting the weighted histogram method:

$$G_0(z) = -\beta^{-1} \ln \frac{\sum_t \frac{\langle \delta(z - z_t) \exp(-\beta w_t) \rangle}{\langle \exp(-\beta w_t) \rangle}}{\sum_t \frac{\exp[-\beta u(z, t)]}{\langle \exp(-\beta w_t) \rangle}}, \quad (3.1.6.18)$$

where the sum is over time slices  $t$  and  $u(z, t) = k(z - vt)^2/2$  is the time dependent biasing potential. As in the weighted histogram method, this procedure can be refined by making Eq. 3.1.6.18 self-consistent through replacement of  $\langle \exp(-\beta w_t) \rangle$  with

$$\exp[-\beta \Delta G(t)] = \frac{\int \exp\{-\beta[u(z, t) + G_0(z)]\} dz}{\int \exp\{-\beta[u(z, 0) + G_0(z)]\} dz}, \quad (3.1.6.19)$$

thus requiring an iterative solution for  $\Delta G(t)$ . Note that Eq. 3.1.6.18 can be rewritten as

$$G_0(z) = -\beta^{-1} \ln \frac{\sum_t \frac{\langle \delta(z - z_t) \exp(-\beta \Delta w_t) \rangle \exp[-\beta u(z, t)]}{\langle \exp(-\beta w_t) \rangle}}{\sum_t \frac{\exp[-\beta u(z, t)]}{\langle \exp(-\beta w_t) \rangle}}, \quad (3.1.6.20)$$

which is the natural logarithm of the weighted average of  $\langle \delta(z - z_t) \exp(-\beta \Delta w_t) \rangle$  over all the time slices with  $\frac{\exp[-\beta u(z, t)]}{\langle \exp(-\beta w_t) \rangle}$  being the weight.

### 3.1.7 Transition-Based Reweighting Analysis Method

Transition-Based Reweighting Analysis Method (TRAM), which relies on the maximum likelihood analysis of the thermodynamic and kinetic information, was developed by Frank Noé and coworkers in 2014.[43]. It incorporates WHAM with Markov state model, and avoids the weakness in both methods. In WHAM, a global equilibrium among all the thermodynamic states must be reached. For the Markov state model (MSM), the kinetic information can be extracted from only one thermodynamic state. In contrast, TRAM is a class of estimators that (1) take the statistical weights of samples at different thermodynamic states into account, and (2) exploit transitions observed in the sampled trajectories, without assuming that these trajectories are sampled from equilibrium.

Let us assume that there are  $K$  molecular dynamics (MD) or Markov chain Monte Carlo (MCMC) simulations have been performed, each in a specific thermodynamic state (Hamiltonian, temperature, etc) indexed by  $k \in \{1, \dots, K\}$ . For simulations with varying thermodynamic state in a single trajectory, with replica-exchange simulation being a typical example, each contiguous sequence is treated as a separated trajectory at one of the  $K$  thermodynamic states. We further assume the configuration space (that has been visited by the simulations) is discretized into cells indexed by  $i, j \in \{1, \dots, n\}$ .

Similar to the WHAM analysis, the unbiased probability,  $\pi_i$ , and the biased probability under thermodynamic state  $k$ ,  $\pi_i^{(k)}$  are related by a known and constant bias factor  $\gamma_i^{(k)}$

$$\pi_i^{(k)} = f^{(k)} \pi_i \gamma_i^{(k)}, \quad (3.1.7.1)$$

$$f^{(k)} = \frac{1}{\sum_l \pi_l \gamma_l^{(k)}}, \quad (3.1.7.2)$$

where  $f^{(k)}$  is a normalization constant. Thus, the bias is multiplicative in probability or additive in the potential. As we have shown in section 3.1.4, the WHAM estimator can be derived by maximizing the likelihood

$$L_{\text{WHAM}} = \prod_k \prod_i (\pi_i^{(k)})^{N_i^{(k)}} \quad (3.1.7.3)$$

with an implied assumption that every count  $N_i^{(k)}$  is independently drawn from the biased distribution  $\pi_i^{(k)}$ .

The maximum likelihood Markov model is the transition matrix  $\mathbf{P} = (p_{ij})$  between  $n$  discrete configuration states, that maximizes the likelihood of the observed transitions between these states. The likelihood of a Markov model is a product of all transition probabilities corresponding to the observed trajectory. To obtain a reversible Markov state model, this likelihood

is maximized under the constraints of detailed balance with respect to the equilibrium distribution  $\boldsymbol{\pi}$

$$L_{\text{MSM}} = \prod_i \prod_j p_{ij}^{c_{ij}}, \quad (3.1.7.4)$$

$$\text{s.t. } \pi_i p_{ij} = \pi_j p_{ji} \quad \text{for all } i, j, \quad (3.1.7.5)$$

where  $c_{ij}$  is the number of times the trajectories were observed in state  $i$  at time  $t$  and in state  $j$  at a later time  $t + \tau$ , where  $\tau$  is the lag time at which the Markov model is estimated.

In TRAM, WHAM and MSM are combined as follows: every trajectory at thermodynamic state  $k$  is treated as a Markov chain with the configuration-state transition counts  $c_{ij}^{(k)}$ , without assuming that every count is sampled from global equilibrium. In contrast to Markov models, we exploit the fact that equilibrium probabilities can be reweighted between different thermodynamic states via Eqs. 3.1.7.1 and 3.1.7.2. The resulting likelihood of all  $\mathbf{P}^{(k)}$  and  $\boldsymbol{\pi}$ , based on simulations at all thermodynamic states can be formulated as

$$L_{\text{TRAM}} = \prod_k \prod_i \prod_j (p_{ij}^{(k)})^{c_{ij}^{(k)}}, \quad (3.1.7.6)$$

$$\text{s.t. } \pi_i^{(k)} p_{ij}^{(k)} = \pi_j^{(k)} p_{ji}^{(k)} \quad \text{for all } i, j, k. \quad (3.1.7.7)$$

Here,  $\mathbf{P}^{(k)} = (p_{ij}^{(k)})$  is the Markov transition matrix at thermodynamic state  $k$ , and  $c_{ij}^{(k)}$  are the number of transitions observed at that simulation condition.  $\boldsymbol{\pi}^{(k)}$  is the vector of equilibrium probabilities of discrete states at each thermodynamic state. *Because each Markov model  $\mathbf{P}^{(k)}$  must have the distribution  $\boldsymbol{\pi}^{(k)}$  as a stationary distribution, all Markov models are coupled too, which makes the maximization of the TRAM likelihood Eqs. 3.1.7.6 and 3.1.7.7 difficult, and it can neither be achieved by WHAM, nor by existing MSM estimators.*

Taking natural logarithm on the TRAM likelihood, we find

$$\ln L_{\text{TRAM}} = \sum_{k=1}^K \sum_{i=1}^n \sum_{j=1}^n c_{ij}^{(k)} \ln p_{ij}^{(k)}, \quad (3.1.7.8)$$

with constraints

$$\pi_i \gamma_i^{(k)} p_{ij}^{(k)} = \pi_j \gamma_j^{(k)} p_{ji}^{(k)} \quad \text{for all } i, j, k, \quad (3.1.7.9)$$

which is from Eqs. 3.1.7.1 and 3.1.7.7 with  $f^{(k)}$  canceled. In addition,  $\mathbf{P}^{(k)}$  and  $\boldsymbol{\pi}$  should satisfy the normalization conditions

$$\sum_j p_{ij}^{(k)} = 1 \quad \forall i, k, \quad (3.1.7.10)$$

$$\sum_j \pi_j = 1. \quad (3.1.7.11)$$

The normalization of  $\boldsymbol{\pi}^{(k)}$  is naturally satisfied due to Eqs. 3.1.7.1 and 3.1.7.2. Due to the existence of constraints, the numbers of free variables are  $n - 1$  for  $\boldsymbol{\pi}$  and  $n(n - 1)/2$  for  $\mathbf{P}^{(k)}$ .

Using the Lagrange duality theory, it can be shown that the optimal solution of the discrete TRAM problem above fulfills the following two conditions

$$\sum_k \sum_j \frac{(c_{ij}^{(k)} + c_{ji}^{(k)})\gamma_i^{(k)}\pi_i\nu_j^{(k)}}{\gamma_i^{(k)}\pi_i\nu_j^{(k)} + \gamma_j^{(k)}\pi_j\nu_i^{(k)}} = \sum_k \sum_j c_{ji}^{(k)}, \quad (3.1.7.12)$$

$$\sum_j \frac{(c_{ij}^{(k)} + c_{ji}^{(k)})\gamma_j^{(k)}\pi_j}{\gamma_i^{(k)}\pi_i\nu_j^{(k)} + \gamma_j^{(k)}\pi_j\nu_i^{(k)}} = 1 \quad (3.1.7.13)$$

where  $\nu_i^{(k)}$  are unknown Lagrange multipliers. To numerically solve the discrete TRAM problem, an initial guess for  $\boldsymbol{\pi}$  and  $\mathbf{v}^{(k)}$  can be made as

$$\pi_i^{init} := 1/n, v_i^{(k),init} := \sum_j c_{ij}^{(k)}, \quad (3.1.7.14)$$

and the following equations must be solved iteratively until  $\boldsymbol{\pi}$  is converged:

$$v_i^{(k),new} := v_i^{(k)} \sum_j \frac{(c_{ij}^{(k)} + c_{ji}^{(k)})\gamma_i^{(k)}\pi_j}{\gamma_i^{(k)}\pi_i\nu_j^{(k)} + \gamma_j^{(k)}\pi_j\nu_i^{(k)}}, \quad (3.1.7.15)$$

$$\pi_i^{new} := \frac{\sum_{k,j} c_{ji}^{(k)}}{\sum_{k,j} \frac{(c_{ij}^{(k)} + c_{ji}^{(k)})\gamma_i^{(k)}\nu_j^{(k)}}{\gamma_i^{(k)}\pi_i\nu_j^{(k)} + \gamma_j^{(k)}\pi_j\nu_i^{(k)}}}. \quad (3.1.7.16)$$

## 3.2 Approximate Methods

### 3.2.1 Molecular Mechanics/Poisson-Boltzmann Surface Area

The following derivation follows Ref. [44]. The Molecular Mechanics/Poisson-Boltzmann Surface Area (MM/PBSA) method is often used in the calculations of binding free energy of a substrate to a receptor. The standard binding free energy for a reaction between a receptor (A) and a substrate (B)

is expressed as a ratio of configuration integrals

$$\begin{aligned} \Delta G_{AB}^0 &= -RT \ln \left( \frac{C^0}{8\pi^2} \cdot \frac{Z_{N,AB} Z_{N,0}}{Z_{N,A} Z_{N,B}} \right) + P^0 \langle \Delta V_{AB} \rangle \\ &= -RT \ln \left( \frac{C^0}{8\pi^2} \cdot \frac{\frac{Z_{N,AB}}{Z_{N,0}}}{\frac{Z_{N,A}}{Z_{N,0}} \frac{Z_{N,B}}{Z_{N,0}}} \right) + P^0 \langle \Delta V_{AB} \rangle, \end{aligned} \quad (3.2.1.1)$$

where  $R$  is the gas constant,  $T$  is the temperature,  $C^0$  is the standard state concentration (1  $M$ ),  $N$  is the number of solvent molecules, and  $P^0 \langle \Delta V_{AB} \rangle$  is the pressure-volume work associated with changing the system size after the association of two species into one complex. For water solution at 1 atm, the last term is negligibly small. There are no mass-dependent terms in Eq. 3.2.1.1, which is a direct result of equal kinetic contribution to the partition function of the bound and the free species. The configuration integral of the receptor, A, in solution is

$$Z_{N,A} = \int e^{-\beta U(r_A, r_S)} dr_A dr_S, \quad (3.2.1.2)$$

where  $U(r_A, r_S)$  is the potential energy as a function of all solute coordinates,  $r_A$ , and solvent coordinates,  $r_S$ , and  $\beta$  is the reciprocal of the product of the Boltzmann constant and temperature. The total potential energy can be decomposed into  $U(r_A) + U(r_S) + \Delta U(r_A, r_S)$ . Similar for  $B$ , the substrate. For pure solvent, the configuration integral is

$$Z_{N,0} = \int e^{-\beta U(r_S)} dr_S. \quad (3.2.1.3)$$

The ratio of configuration integrals in Eq. 3.2.1.1 can be simplified with an implicit solvent approximation, as

$$\begin{aligned} \frac{Z_{N,A}}{Z_{N,0}} &= Z_A = \frac{\int e^{-\beta U(r_A)} \left\{ \int e^{-\beta \Delta U(r_A, r_S)} e^{-\beta U(r_S)} dr_S \right\} dr_A}{\int e^{-\beta U(r_S)} dr_S} \\ &= \int e^{-\beta [U(r_A) + W(r_A)]} dr_A, \end{aligned} \quad (3.2.1.4)$$

where

$$W(r_A) = -RT \ln \left( \frac{\int e^{-\beta \Delta U(r_A, r_S)} e^{-\beta U(r_S)} dr_S}{\int e^{-\beta U(r_S)} dr_S} \right) \quad (3.2.1.5)$$

is the solvation free energy of the receptor  $A$  at fixed coordinate  $r_A$ . Analogous equations hold for the complex and substrate.

For the complex, we define the position (translational degrees of freedom) and orientation (rotational degrees of freedom) of the substrate with respect to the receptor as  $\delta_B \equiv (x_1, x_2, x_3, \xi_1, \xi_2, \xi_3)$ . Generally, these degree-of-freedom is very limited. The complex configuration integral is

$$Z_{AB} = \int e^{-\beta[U(r_A, r_{B'}, \delta_B) + W(r_A, r_{B'}, \delta_B)]} dr_A dr_{B'} d\delta_B, \quad (3.2.1.6)$$

where  $r_{B'}$  represents the remaining internal degrees of freedom of the bound substrate and  $\delta_B$  spans conformations where  $A$  and  $B$  form a complex. Then we assume that the translational and rotational motions of the substrate in the bound state are not strongly coupled with the other degrees of freedom, and we decompose the potential and solvation energies as (*so weird!*)

$$\begin{aligned} U(r_A, r_{B'}, \delta_B) + W(r_A, r_{B'}, \delta_B) \\ \approx U_1(\delta_B) + W_1(\delta_B) + U_2(r_A, r_{B'}) + W_2(r_A, r_{B'}). \end{aligned} \quad (3.2.1.7)$$

We further assume that the residual translational and rotational motions of the substrate are uncorrelated. Therefore

$$U_1(\delta_B) \approx U(x_1, x_2, x_3) + U(\xi_1, \xi_2, \xi_3), \quad (3.2.1.8)$$

and

$$W_1(\delta_B) \approx W(x_1, x_2, x_3) + W(\xi_1, \xi_2, \xi_3). \quad (3.2.1.9)$$

Now, Eq. 3.2.1.1 can be written as

$$\Delta G_{AB}^0 = -RT \ln \left[ \frac{C^0 Z_{B'}^{trans} Z_{B'}^{rot} Z_{AB'}}{8\pi^2 Z_A Z_B} \right], \quad (3.2.1.10)$$

where

$$Z_{B'}^{trans} = \int e^{-\beta[U(x_1, x_2, x_3) + W(x_1, x_2, x_3)]} dx_1 dx_2 dx_3 \quad (3.2.1.11)$$

and

$$Z_{B'}^{rot} = \int e^{-\beta[U(\xi_1, \xi_2, \xi_3) + W(\xi_1, \xi_2, \xi_3)]} d\xi_1 d\xi_2 d\xi_3. \quad (3.2.1.12)$$

As a first-order approximation, we assume that the energetic landscape of each species has an energy and a volume (entropy),

$$Z_A = \int e^{-\beta[U(r_A) + W(r_A)]} dr_A \approx Z_A^{int} e^{-\beta \langle E_A \rangle}, \quad (3.2.1.13)$$

where  $\langle E_A \rangle = \langle U(r_A) + W(r_A) \rangle$ . We further assume (*how many approximations we have taken!*) that  $Z_A^{int} Z_B^{int} \approx Z_{AB}^{int}$ , then

$$\Delta G_{AB}^0 = -RT \ln \left( \frac{C^0 Z_{B'}^{trans} Z_{B'}^{rot}}{8\pi^2} \right) + (\langle E_{AB'} \rangle - \langle E_A \rangle - \langle E_B \rangle). \quad (3.2.1.14)$$

The bound substrate's translational configuration integral,  $Z_{B'}^{trans}$ , can be conceptually linked to the volume of space that its center of mass occupies through the simulation. The effective volume was measured based on the assumption that the translational motion is restrained by three harmonic potential. By solving eigenstates of the center-of-mass covariance matrix, the eigenvalues describe the variance  $\Delta x_i^2$  along each principal axis. Thus, the translational configuration integral can be calculated as

$$\begin{aligned} Z_{B'}^{trans} &= \int e^{(-k_1 \Delta x_1^2 / 2k_B T)} dx_1 \int e^{(-k_2 \Delta x_2^2 / 2k_B T)} dx_2 \int e^{(-k_3 \Delta x_3^2 / 2k_B T)} dx_3 \\ &= (2\pi)^{3/2} \left( \langle \Delta x_1^2 \rangle \langle \Delta x_2^2 \rangle \langle \Delta x_3^2 \rangle \right)^{1/2} \end{aligned} \quad (3.2.1.15)$$

where

$$k_i = \frac{k_B T}{\langle \Delta x_i^2 \rangle}. \quad (3.2.1.16)$$

The rotational configuration integral can be accounted in a similar manner.

## 4

# Evaluation of Reliability

*“A theory is something nobody believes, except the person who made it. An experiment is something everybody believes, except the person who made it.”*

– Albert Einstein,

## 4.1 Overlap Matrix

Overlap matrix proposed by Mobley et. al.,[45] can be used to essentially measures the magnitude of the phase space overlap. For example, after MBAR method is used to analyze the US simulations or a series of alchemical window simulations, the overlap matrix can be used to examine the reliabilities of MBAR calculations. The formula about the overlap matrix is shown as follows:

For the US simulations, with the weight of the  $l$ th configuration in the  $i$ th biased simulation appearing in the  $t$ th simulation defined as

$$w_t(\mathbf{x}_{i,l}) = \frac{e^{-\beta [W_t(\mathbf{x}_{i,l}) - f_t^{(b)}]}}{\sum_{k=1}^S N_k e^{-\beta [W_k(\mathbf{x}_{i,l}) - f_k^{(b)}]}}, \quad (4.1.0.1)$$

the elements of the  $S \times S$  overlap matrix are[45]

$$\begin{aligned} O_{tt'} &= \sum_{i=1}^S \sum_{l=1}^{N_i} N_t w_t(\mathbf{x}_{i,l}) w_{t'}(\mathbf{x}_{i,l}) \\ &= \sum_{i=1}^S \sum_{l=1}^{N_i} \frac{N_t e^{-\beta [W_t(\mathbf{x}_{i,l}) - f_t^{(b)}]} e^{-\beta [W_{t'}(\mathbf{x}_{i,l}) - f_{t'}^{(b)}]}}{\left\{ \sum_{k=1}^S N_k e^{-\beta [W_k(\mathbf{x}_{i,l}) - f_k^{(b)}]} \right\}^2}. \end{aligned} \quad (4.1.0.2)$$

Consecutive windows should have substantial overlap with the diagonal and the first off-diagonal elements no smaller than 0.03 as recommended[45].

For a series of alchemical window simulations, it is a  $K \times K$  matrix with entries

$$O_{ij} = \sum_{n=1}^N \frac{N_i p_i(x_n)}{\sum_{k=1}^K N_k p_k(x_n)} \frac{p_j(x_n)}{\sum_{k=1}^K N_k p_k(x_n)}, \quad (4.1.0.3)$$

where  $p_i(x_n) = e^{\beta G_i - \beta U_i(x_n)}$  is the probability of sample  $x_n$  occurring when simulation state  $i$  and  $N$  samples are collected with  $N_1$  samples from  $p_1(x)$  distribution,  $N_2$  samples from  $p_2(x)$  distribution, and so on.  $K$  is the total number of the states.  $O_{ij}$  can be interpreted as the average probability of a sample generated in state  $j$  being observed in the  $i$ th state. The average is computed over samples collected from all the  $K$  states, not just the samples from state  $j$ . Therefore  $O_{ij}$  is a measure of the overlap in the phase space of state  $i$  and  $j$ . The larger the better. The largest eigenvalue is 1. Similarly, consecutive windows should have substantial overlap with the diagonal and the first off-diagonal elements no smaller than 0.03 as recommended[45].

## 4.2 $\Pi$ Metric for Neglected-tail Bias Model

The neglected-tail bias model is developed by Kofke and coworkers for the estimate of bias in free energy via thermodynamic perturbation or the Jarzynski equality[46, 47]. Here, we will take the latter as an example. Let  $p_A(W)$  and  $p_B(W)$  be the distributions/probabilities of work samples  $W$  in a forward ( $A \rightarrow B$ ) and a backward ( $B \rightarrow A$ ) nonequilibrium conversions. The Jarzynski equality discussed in 3.1.6 shows that the free energy difference is given by

$$\exp(-\beta \Delta A) = \int_{-\infty}^{\infty} p_A(W) e^{-\beta W} dW, \quad (4.2.0.1)$$

or

$$\exp(+\beta \Delta A) = \int_{-\infty}^{\infty} p_B(W) e^{+\beta W} dW. \quad (4.2.0.2)$$

These two distributions are related

$$p_A(W) e^{-\beta W} = p_B(W) e^{-\beta \Delta A}. \quad (4.2.0.3)$$

The neglected-tail bias model asserts that *all* of the bias is due the neglect of contributions below a particular value of  $W$ , designated as  $W^*$ , such that no sampling is contributed below this value, and *perfect sampling* is achieved for  $W > W^*$ .

It can be easily imagined that  $W^*$  depends on the sample size. When more sampling is performed, more likely a more negative value of  $W^*$  will

be encountered. Given  $p_A(W)$ , the probability distribution for  $W^*$  being observed once within  $M$  samples is

$$P_A^*(W^*) = Mp_A(W^*)[1 - C_A(W^*)]^{M-1}, \quad (4.2.0.4)$$

where  $C_A(W)$  is the cumulative distribution function defined as

$$C_A(W^*) = \int_{-\infty}^{W^*} p_A(W) dW \quad (4.2.0.5)$$

and

$$1 - C_A(W^*) = \int_{W^*}^{\infty} p_A(W) dW. \quad (4.2.0.6)$$

The bias can be written as

$$\begin{aligned} B(M) &= \langle \Delta A(M) \rangle - \Delta A \\ &= -kT \ln \left[ \frac{1}{M} \left( e^{-\beta W^*} + (M-1) \times \frac{\int_{W^*}^{\infty} dW e^{-\beta W} p_A(W)}{1 - C_A(W^*)} \right) \right] - \Delta A \\ &= -kT \ln \left[ \frac{1}{M} \left( e^{-\beta W_{dis}^*} + (M-1) \times \frac{1 - C_B(W^*)}{1 - C_A(W^*)} \right) \right], \end{aligned} \quad (4.2.0.7)$$

where

$$W_{dis} = W - \Delta A \quad (4.2.0.8)$$

is the dissipated work. For the third equality, we have employed Eq. 4.2.0.3. The bias can be evaluated as the average of the inaccuracy over the distribution of  $W^*$

$$B(M) = -kT \int_{-\infty}^{\infty} dW^* P_A^*(W^*) \ln \left[ \frac{1}{M} \left( e^{-\beta W_{dis}^*} + (M-1) \times \frac{1 - C_B(W^*)}{1 - C_A(W^*)} \right) \right]. \quad (4.2.0.9)$$

Alternatively, it can be estimated for a single value of  $W^*$ , for instance the mode  $\hat{W}^*$  of  $P_A^*$ . It follows from

$$\left. \frac{d \ln P_A(W^*)}{dW^*} \right|_{W=\hat{W}^*} = 0 \quad (4.2.0.10)$$

and is given by the solution of

$$\left. \frac{d \ln p_A(W)}{dW} \right|_{W=\hat{W}^*} = \frac{(M-1)p_A(\hat{W}^*)}{1 - C_A(\hat{W}^*)}. \quad (4.2.0.11)$$

or, with a small approximation

$$\left. \frac{d \ln p_A(W)}{dW} \right|_{W=\hat{W}^*} = (M-1)p_A(\hat{W}^*). \quad (4.2.0.12)$$

Assuming  $W^*$  has a Gaussian distribution centered at  $\hat{W}^*$  as

$$P_A^*(W^*) \approx \frac{1}{\sqrt{2\pi}\sigma^*} \exp \left[ -(W^* - \hat{W}^*)^2 / 2\sigma^{*2} \right] \quad (4.2.0.13)$$

in which, using Eq. 4.2.0.4 and the property in Eq. 4.2.0.11,

$$\frac{1}{\sigma^{*2}} = -\frac{d^2 \ln P_A^*}{dW^{*2}} = -\left[ \frac{\partial^2 \ln p_A}{\partial W^2} - \frac{M}{M-1} \left( \frac{\partial \ln p_A}{\partial W} \right)^2 \right] \Big|_{W=\hat{W}^*}. \quad (4.2.0.14)$$

Corresponding relations can be given for the bias of the  $B \rightarrow A$  work process. Thus from the work distributions the expected performance of a simulation of given sampling length can be predicted.

Next, let us look at the work distributions. We assume a Gaussian-work distribution

$$p_A(W) = \frac{1}{\sqrt{2\pi}\sigma} \exp \left[ -(W - \bar{W})^2 / 2\sigma^2 \right]. \quad (4.2.0.15)$$

From Eq. 4.2.0.3, it can be found that  $p_B(W)$  is also a Gaussian with the same variance but shifted by  $\beta\sigma^2$

$$p_B(W) = \frac{1}{\sqrt{2\pi}\sigma} \exp \left[ -(W - \bar{W} + \beta\sigma^2)^2 / 2\sigma^2 \right]. \quad (4.2.0.16)$$

The free energy difference is

$$\Delta A = \bar{W} - \beta\sigma^2. \quad (4.2.0.17)$$

The cumulative distribution functions are

$$C_A(W) = \frac{1}{2} \operatorname{erfc} \left( \frac{\bar{W} - W}{\sqrt{2}\sigma} \right), \quad (4.2.0.18)$$

$$C_B(W) = \frac{1}{2} \operatorname{erfc} \left( \frac{\bar{W} - \beta\sigma^2 - W}{\sqrt{2}\sigma} \right), \quad (4.2.0.19)$$

where  $\operatorname{erfc}(x)$  is the complementary error function.

By taking Eq. 4.2.0.15 into Eq. 4.2.0.12, the mode of the least-work distribution is approximately

$$\hat{W}^* = \bar{W} - \sigma \sqrt{\mathbf{W}_L \left[ \frac{1}{2\pi} (M-1)^2 \right]}, \quad (4.2.0.20)$$

where  $\mathbf{W}_L(x)$  is the Lambert  $W$  function, defined as the solution to  $x = we^w$ . With a slight approximation to Eq. 4.2.0.7 as

$$B(M) = -kT \ln [1 - C_B(W^*)] \quad (4.2.0.21)$$

and this estimated mode used for  $W^*$ , this Gaussian-work bias becomes

$$B(M) = -kT \ln \left\{ \frac{1}{2} \operatorname{erfc} \left[ -\frac{1}{\sqrt{2}} \left( \sqrt{\mathbf{W}_L \left[ \frac{1}{2\pi} (M-1)^2 \right]} - \beta\sigma \right) \right] \right\}, \quad (4.2.0.22)$$

and depends solely on

$$\Pi = \sqrt{\mathbf{W}_L \left[ \frac{1}{2\pi} (M-1)^2 \right]} - \beta\sigma. \quad (4.2.0.23)$$

By using Eq. 4.2.0.17, it can be rewritten as

$$\Pi = \sqrt{\mathbf{W}_L \left[ \frac{1}{2\pi} (M-1)^2 \right]} - \sqrt{2\beta(\bar{W} - \Delta A)}. \quad (4.2.0.24)$$

Wu and Kofke suggested that the number of work samples (non-equilibrium trajectories) should be sufficient to ensure  $\Pi > 0.5$ . [47]

### 4.3 Kullback–Leibler divergence

The convergence rate of thermodynamic perturbation heavily depends on the similarity between the simulated Hamiltonian (A) and the target one (B). Kullback–Leibler divergence offers a quantitative way to measure the similarity by

$$s_A = \int_{\Gamma} d\mathbf{x} p_A(\mathbf{x}) \ln \left[ \frac{p_A(\mathbf{x})}{p_B(\mathbf{x})} \right]. \quad (4.3.0.1)$$

$s_A$  is also known as the relative entropy in Information theory. Similarly, we can also have

$$s_B = \int_{\Gamma} d\mathbf{x} p_B(\mathbf{x}) \ln \left[ \frac{p_B(\mathbf{x})}{p_A(\mathbf{x})} \right]. \quad (4.3.0.2)$$

With the Boltzmann statistics,

$$p_A(\mathbf{x}) = e^{-\beta U(\mathbf{x})} / Q_A. \quad (4.3.0.3)$$

The relative entropies can be written as

$$\begin{aligned} s_A &= \int_{\Gamma} d\mathbf{x} \frac{e^{-\beta U_A(\mathbf{x})}}{Q_A} \ln \left[ \frac{e^{-\beta U_A(\mathbf{x})}}{Q_A} \frac{Q_B}{e^{-\beta U_B(\mathbf{x})}} \right] \\ &= \int_{\Gamma} d\mathbf{x} \frac{e^{-\beta U_A(\mathbf{x})}}{Q_A} \{ \beta [U_B(\mathbf{x}) - U_A(\mathbf{x})] - \beta \Delta A \} \end{aligned} \quad (4.3.0.4)$$

$$= \beta \langle \Delta U \rangle_A - \beta \Delta A \quad (4.3.0.5)$$

and

$$s_B = -\beta \langle \Delta U \rangle_B + \beta \Delta A, \quad (4.3.0.6)$$

which are exactly the dissipated work [48].

## Appendix A

# Statistical Uncertainty in the Estimator for Correlated Time Series Data

*“It is not the estimate or the forecast that matters so much as the degree of confidence with the opinion.”*

– Nassim Nicholas Taleb

Suppose we have a time series of correlated sequential observations of the randomly sampled variable  $X$  denoted as  $\{x_n\}, n = 1, \dots, N$  that come from a stationary, time-reversible stochastic process. The expectation of  $X$  can be estimated as the time average of the samples

$$\hat{X} = \frac{1}{N} \sum_{n=1}^N x_n. \quad (\text{A.0.0.1})$$

Because of the existence of correlation among the samples, the variance for the expectation, which is defined as

$$\delta^2 \hat{X} \equiv \left\langle \left( \hat{X} - \langle \hat{X} \rangle \right)^2 \right\rangle = \langle \hat{X}^2 \rangle - \langle \hat{X} \rangle^2, \quad (\text{A.0.0.2})$$

is complicated. We first take Eq. A.0.0.1 into Eq. A.0.0.2, and split the sum into one term capturing the variance in the observations and a remaining term capturing the correlation between the observations as

$$\begin{aligned} \delta^2 \hat{X} &= \frac{1}{N^2} \sum_{n,n'=1}^N [\langle x_n x_{n'} \rangle - \langle x_n \rangle \langle x_{n'} \rangle] \\ &= \frac{1}{N^2} \sum_{n=1}^N \left[ \langle x_n^2 \rangle - \langle x_n \rangle^2 \right] + \frac{1}{N^2} \sum_{n \neq n'=1}^N [\langle x_n x_{n'} \rangle - \langle x_n \rangle \langle x_{n'} \rangle] \quad (\text{A.0.0.3}) \end{aligned}$$

Because of the stationarity, it becomes

$$\begin{aligned}\delta^2 \hat{X} &= \frac{1}{N} \left[ \langle x_n^2 \rangle - \langle x_n \rangle^2 \right] \\ &\quad + \frac{1}{N^2} \sum_{t=1}^{N-1} (N-t) [\langle x_n x_{n+t} \rangle + \langle x_{n+t} x_n \rangle - \langle x_n \rangle \langle x_{n+t} \rangle - \langle x_{n+t} \rangle \langle x_n \rangle] \end{aligned} \quad (\text{A.0.0.4})$$

and because of the time-reversibility, it can be further simplified to

$$\begin{aligned}\delta^2 \hat{X} &= \frac{1}{N} \left[ \langle x_n^2 \rangle - \langle x_n \rangle^2 \right] \\ &\quad + \frac{2}{N} \sum_{t=1}^{N-1} \left( \frac{N-t}{N} \right) [\langle x_n x_{n+t} \rangle - \langle x_n \rangle \langle x_{n+t} \rangle] \\ &\equiv \frac{\sigma_x^2}{N} (1 + 2\tau) = \frac{\sigma_x^2}{N/g}, \end{aligned} \quad (\text{A.0.0.5})$$

where  $\sigma_x^2$ , statistical inefficiency  $g$ , and autocorrelation time  $\tau$  (in units of the sampling interval) are given by

$$\sigma_x^2 \equiv \langle x_n^2 \rangle - \langle x_n \rangle^2 \quad (\text{A.0.0.6})$$

$$\tau \equiv \sum_{t=1}^{N-1} \left( \frac{N-t}{N} \right) C_t \quad (\text{A.0.0.7})$$

$$C_t = \frac{\langle x_n x_{n+t} \rangle - \langle x_n \rangle \langle x_n \rangle}{\sigma_x^2} \quad (\text{A.0.0.8})$$

$$g \equiv 1 + 2\tau \quad (\text{A.0.0.9})$$

The quantity  $g \equiv 1 + 2\tau > 1$  can be regarded as a statistical inefficiency, in that  $N/g$  gives the effective number of *uncorrelated* configurations contained in the time series.

## Appendix B

# The Optimal Mean of Independent Measurements with Uncertainties

Suppose we have  $N$  measurements of a quantity  $x$ , which are denoted as  $\{x_i\}$ , with  $i = 1, \dots, N$ . Each measurement has a variance  $\delta^2 x_i$ . To find the optimal mean of this data set, we first write the mean of  $\{x_i\}$  as a weighted average of them

$$\bar{x} = \sum_{i=1}^N a_i x_i, \quad (\text{B.0.0.1})$$

in which  $a_i$  are the normalized weights, i.e.

$$\sum_{i=1}^N a_i = 1. \quad (\text{B.0.0.2})$$

According to the error propagation rule, if the measurements are independent, the variance of the mean  $\bar{x}$  can be written as

$$\delta^2 \bar{x} = \sum_{i=1}^N a_i^2 \delta^2 x_i. \quad (\text{B.0.0.3})$$

Minimizing  $\delta^2 \bar{x}$  with respect to  $a_i$  under the constraint of Eq. B.0.0.2 using the Lagrange multiplier  $\lambda$ , we find

$$\begin{aligned} \frac{\partial L}{\partial a_j} &= \frac{\partial}{\partial a_j} \left[ \sum_{i=1}^N a_i^2 \delta^2 x_i + \lambda \left( 1 - \sum_{i=1}^N a_i \right) \right] \\ &= 2a_j \delta^2 x_j - \lambda \\ &= 0 \end{aligned} \quad (\text{B.0.0.4})$$

for all  $x_j$ . It can be easily identified that  $a_j$  is inversely proportional to  $\delta^2 x_j$ , i.e.

$$a_j = \frac{(\delta^2 x_j)^{-1}}{\sum_{i=1}^N (\delta^2 x_i)^{-1}}, \quad (\text{B.0.0.5})$$

and

$$\bar{x} = \sum_{j=1}^N \frac{(\delta^2 x_j)^{-1}}{\sum_{i=1}^N (\delta^2 x_i)^{-1}} x_j, \quad (\text{B.0.0.6})$$

with

$$\delta^2 \bar{x} = \sum_{j=1}^N \frac{(\delta^2 x_j)^{-1}}{\left( \sum_{i=1}^N (\delta^2 x_i)^{-1} \right)^2} = \frac{1}{\sum_{i=1}^N (\delta^2 x_i)^{-1}}. \quad (\text{B.0.0.7})$$

## Appendix C

# The Relationship between the $\Delta U$ Distributions in Forward and Backward TP

In a forward TP calculation between  $H_0$  and  $H_1$ , the distribution of  $\Delta U$  is

$$f(\Delta U) = \frac{\int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx}{\int e^{-\beta H_0} dx}. \quad (\text{C.0.0.1})$$

While in a backward TP, the distribution is

$$\begin{aligned} g(\Delta U) &= \frac{\int e^{-\beta H_1} \delta(H_1 - H_0 - \Delta U) dx}{\int e^{-\beta H_1} dx} \\ &= \frac{f(\Delta U) \int e^{-\beta H_1} \delta(H_1 - H_0 - \Delta U) dx \int e^{-\beta H_0} dx}{\int e^{-\beta H_1} dx \int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx} \\ &= f(\Delta U) \frac{\int e^{-\beta H_0} dx \int e^{-\beta H_1} \delta(H_1 - H_0 - \Delta U) dx}{\int e^{-\beta H_1} dx \int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx} \\ &= f(\Delta U) e^{\beta \Delta A} \frac{\int e^{-\beta \Delta H} e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx}{\int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx} \\ &= f(\Delta U) e^{\beta \Delta A} \frac{e^{-\beta \Delta U} \int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx}{\int e^{-\beta H_0} \delta(H_1 - H_0 - \Delta U) dx} \\ &= f(\Delta U) e^{\beta \Delta A} e^{-\beta \Delta U} \end{aligned} \quad (\text{C.0.0.2})$$

Or it can be written as

$$g(\Delta U) e^{\beta \Delta U} = f(\Delta U) e^{\beta \Delta A}, \quad (\text{C.0.0.3})$$

which was first shown by Shing and Gubbins for Widom insertion and deletion[49].

By looking at this equation and the integral in energy space for TP (Eq. 3.1.1.15),

$$\Delta A = -\frac{1}{\beta} \ln \int \exp(-\beta \Delta U) f(\Delta U) d\Delta U, \quad (\text{C.0.0.4})$$

it can be easily realized that the integrand is proportional to the probability of energy difference sampled from state 1 ( $g(\Delta U)$ ) and the free energy difference  $\Delta A$  can be estimated reliably only when the sampling at state 0 covers the representative configurations of state 1.

## Appendix D

# Cumulant Expansion for the Free Energy Difference in Thermodynamic Perturbation Calculations

In Thermodynamic Perturbation, the free energy difference between states are expressed as

$$\Delta A = -\beta^{-1} \ln \langle \exp [-\beta \Delta U] \rangle_0. \quad (\text{D.0.0.1})$$

Due to the exponential term on the right-hand-side of this equation, the convergence is usually slow. This expression can be expanded into Taylor series, and the leading terms can converge much faster than the complete sum.

Using the Taylor expansion for  $e^x = 1 + \sum_{n=1}^{\infty} \frac{1}{n!} x^n$  first, we have

$$\exp [-\beta \Delta U] = 1 + (-\beta \Delta U) + \frac{1}{2!} (-\beta \Delta U)^2 + \frac{1}{3!} (-\beta \Delta U)^3 + \cdots. \quad (\text{D.0.0.2})$$

Then Eq. D.0.0.1 becomes

$$\Delta A = -\beta^{-1} \ln \left( 1 - \beta \langle \Delta U \rangle_0 + \frac{1}{2} \beta^2 \langle \Delta U^2 \rangle_0 - \frac{1}{6} \beta^3 \langle \Delta U^3 \rangle_0 + \cdots \right). \quad (\text{D.0.0.3})$$

Using the Taylor expansion for  $\ln(1+x) = x - \frac{1}{2}x^2 + \frac{2}{3!}x^3 - \frac{6}{4!}x^4 + \cdots$ , we

have

$$\begin{aligned}
\Delta A &= \langle \Delta U \rangle_0 - \frac{1}{2} \beta \langle \Delta U^2 \rangle_0 + \frac{1}{6} \beta^2 \langle \Delta U^3 \rangle_0 + \dots \\
&\quad + \frac{1}{2} \left( \beta \langle \Delta U \rangle_0^2 - \beta^2 \langle \Delta U \rangle_0 \langle \Delta U^2 \rangle_0 + \frac{1}{4} \beta^3 \langle \Delta U^2 \rangle_0^2 + \dots \right) \\
&\quad - \frac{1}{3} \left( -\beta^2 \langle \Delta U \rangle_0^3 + \dots \right) \\
&\quad + \dots \\
&= \langle \Delta U \rangle_0 - \frac{\beta}{2} \left( \langle \Delta U^2 \rangle_0 - \langle \Delta U \rangle_0^2 \right) \\
&\quad + \frac{\beta^2}{6} \left( \langle \Delta U^3 \rangle_0 - 3 \langle \Delta U^2 \rangle_0 \langle \Delta U \rangle_0 + 2 \langle \Delta U \rangle_0^3 \right) + \dots \quad (\text{D.0.0.4})
\end{aligned}$$

## Appendix E

# MBAR Returns to BAR When Only Two States Are Considered

When there are only two states, the free energy in Eq. 3.1.5.7 for the 1st state in MBAR becomes

$$\begin{aligned} f_1 &= -\beta_1^{-1} \ln \sum_{n=1}^N \frac{\exp(-\beta_1 U_1(\mathbf{R}_n))}{\sum_{k=1}^2 N_k \exp(\beta_k f_k - \beta_k U_k(\mathbf{R}_n))} \\ &= -\beta_1^{-1} \ln \sum_{j=1}^2 \sum_{n=1}^{N_j} \frac{\exp(-\beta_1 U_1(\mathbf{R}_{jn}))}{\sum_{k=1}^2 N_k \exp(\beta_k f_k - \beta_k U_k(\mathbf{R}_{jn}))}, \end{aligned} \quad (\text{E.0.0.1})$$

or equivalently we have

$$1 = \sum_{n=1}^N \frac{\exp(\beta_1 f_1 - \beta_1 U_1(\mathbf{R}_n))}{N_1 \exp(\beta_1 f_1 - \beta_1 U_1(\mathbf{R}_n)) + N_2 \exp(\beta_2 f_2 - \beta_2 U_2(\mathbf{R}_n))}, \quad (\text{E.0.0.2})$$

$$\begin{aligned} N_1 &= \sum_{n=1}^{N_1} \frac{1}{1 + \frac{N_2}{N_1} \exp(\Delta f - \Delta U(\mathbf{R}_{1n}))} \\ &\quad + \sum_{n=1}^{N_2} \frac{1}{1 + \frac{N_2}{N_1} \exp(\Delta f - \Delta U(\mathbf{R}_{2n}))} \end{aligned} \quad (\text{E.0.0.3})$$

where  $\Delta f = \beta_2 f_2 - \beta_1 f_1$  and  $\Delta U = \beta_2 U_2 - \beta_1 U_1$ . We further define  $M = -\ln \frac{N_2}{N_1}$ , then

$$\begin{aligned}
N_1 &= \sum_{n=1}^{N_1} \frac{1}{1 + \exp(\Delta f - \Delta U(\mathbf{R}_{1n}) - M)} \\
&\quad + \sum_{n=1}^{N_2} \frac{1}{1 + \exp(\Delta f - \Delta U(\mathbf{R}_{2n}) - M)} \\
0 &= \sum_{n=1}^{N_1} \left[ \frac{1}{1 + \exp(\Delta f - \Delta U(\mathbf{R}_{1n}) - M)} - 1 \right] \\
&\quad + \sum_{n=1}^{N_2} \frac{1}{1 + \exp(\Delta f - \Delta U(\mathbf{R}_{2n}) - M)} \\
\sum_{n=1}^{N_1} \frac{1}{1 + \exp(-\Delta f + \Delta U(\mathbf{R}_{1n}) + M)} &= \sum_{n=1}^{N_2} \frac{1}{1 + \exp(\Delta f - \Delta U(\mathbf{R}_{2n}) - M)} \\
\sum_{n=1}^{N_1} f(-\Delta f + \Delta U(\mathbf{R}_{1n}) + M) &= \sum_{n=1}^{N_2} f(\Delta f - \Delta U(\mathbf{R}_{2n}) - M) \\
N_1 \langle f(-\Delta f + \Delta U(\mathbf{R}_{1n}) + M) \rangle_1 &= N_2 \langle f(\Delta f - \Delta U(\mathbf{R}_{2n}) - M) \rangle_2 \\
\frac{\langle f(\Delta f - \Delta U(\mathbf{R}_{2n}) - M) \rangle_2}{\langle f(-\Delta f + \Delta U(\mathbf{R}_{1n}) + M) \rangle_1} &= \frac{N_1}{N_2},
\end{aligned}$$

which is Eq. 3.1.3.12.

## Appendix F

# MBAR is a binless form of WHAM

Maybe you have already noticed that MBAR and WHAM have very similar forms for the free energy. So you may want to ask if there is any connection between MBAR and WHAM. The answer is YES. MBAR is a binless form of WHAM.[37] Let us follow Zhang et al[50] and rewrite Eq. 3.1.4.20 into an integral form

$$f_i = -\ln \int \Omega \exp(-\beta_i U) dU. \quad (\text{F.0.0.1})$$

Taking Eq. 3.1.4.19 into Eq. F.0.0.1, we find

$$f_i = -\ln \int \frac{\sum_{k=1}^K H_k(U) \exp(-\beta_i U)}{\sum_{k=1}^K N_k \exp(f_k - \beta_k U)} dU, \quad (\text{F.0.0.2})$$

where  $g_{mk}^{-1}$  has been omitted and  $H_{mk}$  has been changed to continuous form  $H_k(U)$ . From the definition,

$$H_k(U) = \sum_{\mathbf{R}}^{(k)} \delta(U(\mathbf{R}) - U). \quad (\text{F.0.0.3})$$

Taking Eq. F.0.0.3 into Eq. F.0.0.2, we have

$$\begin{aligned} f_i &= -\ln \sum_{k=1}^K \sum_{\mathbf{R}}^{(k)} \frac{\exp(-\beta_i U(\mathbf{R}))}{\sum_{k=1}^K N_k \exp(f_k - \beta_k U(\mathbf{R}))} \\ &= -\ln \sum_{n=1}^N \frac{\exp(-\beta_i U_i(\mathbf{R}_n))}{\sum_{k=1}^K N_k \exp(f_k - \beta_k U_k(\mathbf{R}_n))}, \end{aligned} \quad (\text{F.0.0.4})$$

which is Eq. 3.1.5.7.
